Abstract. We consider the distributed implementability problem as: Given a labeled transition system TS together with a distribution Δ of its actions over a set of processes, does there exist a distributed system over Δ such that its global transition system is ‘equivalent’ to TS ? We consider the distributed system models of synchronous products of transition systems [Arn94] and asynchronous automata [Zie87]. In this paper we provide complexity bounds for the above problem with three interpretations of ‘equivalent’: as transition system isomorphism, as language equivalence, and as bisimilarity. In particular, we solve problems left open in [CMT99,Mor99]. We also describe a logic programming implementation which complements the implementation for the synthesis of asynchronous automata initiated in [SEM03].

1 Introduction

In this paper we study the computational complexity of the distributed synthesis problem. The problem has different versions, which share the following abstract formulation: Given a labeled transition system together with a *distribution* (as a relation telling which actions can be executed by which local agents), does there exist a *distributed system* over the given distribution that is behaviourally equivalent to the transition system?

The distributed synthesis problem has been studied for a number of abstract models of distributed systems (elementary net systems, place/transition Petri nets, synchronous products of transition systems [Arn94], and Zielonka’s asynchronous automata [Zie87]) using a number of behavioural equivalences between the implementation and the specification (isomorphism, language equivalence, and bisimilarity). For nearly all these variants, axiomatic or language theoretic characterizations of the transition systems that can be distributed have been provided [ER90,NRT92,Mor98,CMT99,Vog99,Muk02]. Moreover, the computational complexity of the variants concerning elementary net systems and place/transition Petri nets is well understood [BBD95,BBD97]. However, the complexity of many variants concerning synchronous products and asynchronous automata were still open. In this paper we fill many of these gaps, and in particular solve some problems left open in [CMT99,Mor99].

Mukund [Muk02] surveys (structural, behavioural) characterizations for synchronous products and asynchronous automata. In this paper we provide (the

Table 1. Implementability of synchronous products with one initial state

Acyclic & Nondet.	NP-complete	coNP-complete	P
Acyclic & Determ.	P [Mor98]	P	

missing) lower and upper bounds for all the implementability tests presented in [Muk02]. Tables 1,2 present a summary of the known and the new results. Note that, due to slightly different existing characterizations, the two models consider one, respectively multiple initial states. Also, we consider special cases in which the input transition system is assumed to be deterministic or acyclic (column 1).

In [Mor98], Morin proved that distributed implementability modulo isomorphism (column 2) can be solved in polynomial time when the input transition system is deterministic (the result holds for both synchronous products and asynchronous automata). In the nondeterministic case, results from [CMT99,Mor99] show that the problem is in NP, but precise lower bounds were explicitly left open. We show that the problem is NP-complete, even for acyclic specifications.

In [Muk02], Mukund characterized the transition systems that can be implemented as a synchronous product modulo language equivalence. It is not difficult to see that this characterization leads to a PSPACE algorithm. We show that the problem is PSPACE-complete, even if the input transition system is deterministic, and coNP-complete if it is acyclic (Table 1, column 3). We also obtain the same results for the implementability problem modulo bisimulation *when the implementation is required to be deterministic* (Table 1, column 4). (Notice that this is a natural constraint in many areas of hardware design.)

In [Zie89], Zielonka characterized the transition systems that can be implemented as an asynchronous automata modulo language equivalence. Combining this result with several others from the literature, we show that the implementability problem has the same complexity as for synchronous products in the nondeterministic case, but can be solved in polynomial time in the deterministic case (Table 2, column 3). Maybe surprisingly, a simple trick allows us to extend this result to the implementability problem modulo bisimulation, again when the implementation is required to be deterministic (Table 2, column 4).

Partly motivated by the complexity results, in the last part of the paper we present new prototype implementations for asynchronous automata synthesis

problems. The used approach is based on mapping the problems to the problem of finding a stable model of a logic program (an NP-complete problem) by using the SMODELS logic programming system [SNS02].

The paper is organized as follows. We start defining the distributed systems and their associated synthesis problem (Section 2). Sections 3,4,5 present the complexity bounds for the implementability problem, while Section 6 discusses some heuristic implementations for asynchronous automata. The last section is reserved for conclusions and some of the technical details can be found in several appendices.

2 The Implementability Problem for Distributed Systems

We begin with the general notion of a transition system. A *(labeled) transition system* is a tuple $TS = (Q, \Sigma, \rightarrow, I)$, where Q denotes the set of states, Σ the nonempty, finite alphabet of *actions*, $\rightarrow \subseteq Q \times \Sigma \times Q$ the transition relation, and $I \subseteq Q$ the set of initial states. We write $q \xrightarrow{a} q'$ to denote $(q, a, q') \in \rightarrow$. A transition system is called: *deterministic* if $|I| = 1$ and if $q \xrightarrow{a} q'$ and $q \xrightarrow{a} q''$ implies $q' = q''$; *reachable* if $\forall q \in Q \exists q^{in} \in I, w \in \Sigma^* : q^{in} \xrightarrow{w} q$; and *finite* if Q is finite. All transition systems in this paper are considered to be finite and reachable.

To model synchronization, we need as ingredient the notion of *distributed alphabet* or (shorter) *distribution*: A *distribution* is a tuple $(\Sigma, Proc, \Delta)$, where Σ is a nonempty, finite set of *actions*, $Proc$ is a nonempty, finite set of *process labels*, and $\Delta \subseteq \Sigma \times Proc$ is a relation between actions and processes such that each action is in relation with at least one process and vice versa. Δ provides for each action the (nonempty) set of processes that are able to execute that action through the function $dom : \Sigma \rightarrow 2^{Proc}$ defined as $dom(a) := \{p \in Proc \mid (a, p) \in \Delta\}$. Dually, Δ provides for each process the (nonempty) set of actions that may be executed by that process through the function $\Sigma_{loc} : Proc \rightarrow 2^\Sigma$ defined as $\Sigma_{loc}(p) := \{a \in \Sigma \mid (a, p) \in \Delta\}$. In unequivocal contexts we will simply use Δ to denote $(\Sigma, Proc, \Delta)$.

The two models of *distributed transition systems* considered in this paper are based on *synchronization on common actions* for a family of (local) transition systems: We study the (well known) *synchronous products of transition systems* [Arn94] and a generalization of them, *asynchronous automata* [Zie87].

Let $(\Sigma, Proc, \Delta)$ be a distribution. In the first synchronization model, we associate a local transition system with *each process* in $Proc$. A synchronization on a common action $a \in \Sigma$ occurs only when all the local states of the processes in $dom(a)$ enable a and execute it (i.e., update their local states). In the second synchronization model, we associate a transition relation with *each action* $a \in \Sigma$. A synchronization on a occurs only when the tuple of the local states of the processes in $dom(a)$ enable a in the ‘hand-shake’ relation associated with a (the local states are then updated according to this ‘hand-shake’). In both cases, the execution of a only changes the local states of the processes in $dom(a)$.

Definition 1. A *synchronous product of transition systems* \mathcal{SP} over a distribution $(\Sigma, Proc, \Delta)$ is a transition system $(Q, \Sigma, \rightarrow, I)$ for which there exist a family of local state sets $(Q_p)_{p \in Proc}$ and a family of local transition relations $(\rightarrow_p)_{p \in Proc}$ with $\rightarrow_p \subseteq Q_p \times \Sigma_{loc}(p) \times Q_p$ such that:

$$Q \subseteq \prod_{p \in Proc} Q_p \text{ and } Q \text{ consists of all the states reachable from } I \text{ by}$$

$$(q_p)_{p \in Proc} \xrightarrow{a} (q'_p)_{p \in Proc} \Leftrightarrow \begin{cases} q_p \xrightarrow{a}_p q'_p & \text{for all } p \in dom(a) \text{ and} \\ q_p = q'_p & \text{for all } p \notin dom(a). \end{cases}$$

Definition 2. An *asynchronous automaton* \mathcal{AA} over a distribution $(\Sigma, Proc, \Delta)$ is a transition system $(Q, \Sigma, \rightarrow, I)$ for which there exist a family of local state sets $(Q_p)_{p \in Proc}$ and a transition relation $\rightarrow_a \subseteq \prod_{p \in dom(a)} Q_p \times \prod_{p \in dom(a)} Q_p$ for each $a \in \Sigma$, such that:

$$Q \subseteq \prod_{p \in Proc} Q_p \text{ and } Q \text{ consists of all the states reachable from } I \text{ by}$$

$$(q_p)_{p \in Proc} \xrightarrow{a} (q'_p)_{p \in Proc} \Leftrightarrow \begin{cases} (q_p)_{p \in dom(a)} \rightarrow_a (q'_p)_{p \in dom(a)} \text{ and} \\ q_p = q'_p & \text{for all } p \notin dom(a). \end{cases}$$

The problem whose computational complexity we will study in this paper is:

Problem 3. Given a distribution $(\Sigma, Proc, \Delta)$ and a finite transition system TS , does there exist a *distributed transition system* over Δ *equivalent* to TS ?

Mukund [Muk02] surveyed solutions for the above problem when the ‘distributed transition system’ is one of $\{\textit{synchronous product of transition systems, asynchronous automaton}\}$ and ‘equivalent’ is one of $\{\textit{isomorphic, language equivalent, bisimilar}^1\}$. Mukund presents characterizations results without a computational complexity analysis viewpoint. Since we are interested to know which cases are tractable in practice, in this paper we study the complexity of the implementability problem (in many cases, solving this problem also provides an implementation). We follow the presentation of [Muk02] and in addition we study the special cases when the input transition system is supposed to be *deterministic* and/or *acyclic*, for which the complexity results turn out to be usually more favorable. Also, we go a bit more general, allowing the (nondeterministic) distributed systems (Def. 1, 2) to have a set of initial states as opposed to only one initial state in [Muk02].

3 Implementability modulo Isomorphism

This section presents the complexity of checking whether an input transition system is isomorphic to the global state space of a distributed transition system.

We mention that, although in practice the initial specification is usually not isomorphic to a distributed transition system, the synthesis modulo isomorphism is still of relevance because it can be used to guide heuristics of constructing a distributed system exhibiting the same behaviour with the specification (see for instance the approach of [SEM03] for the synthesis of asynchronous automata).

¹This case was only solved for *deterministic* distributed implementations [CMT99].

3.1 Synchronous Products of Transition Systems

The *theory of regions* [ER90] proposed an approach of solving the synthesis modulo isomorphism for Petri nets. Along the same lines goes Theorem 4 below that characterizes the transition systems for which there exists an isomorphic synchronous product of transition systems. If such synchronous product exists, each of its local states Q_p (cf. Def. 1) is constructed as the quotient of the input state space under a local equivalence relation \equiv_p . These equivalences must be chosen such that the following hold: (SP1) an a -labeled transition does not affect the local states of the processes *not contained* in $\text{dom}(a)$; (SP2) the global state space is no more than the cartesian product of the Q_p 's; and (SP3) for an action $a \in \Sigma$, if the local states of the processes in $\text{dom}(a)$ are able to perform an a -labeled transition, then a global synchronization must also be possible.

To simplify the notation, we use the following convention: For two given sets I and J such that $J \subseteq I$ and a given indexed family of binary relations $(\equiv_i)_{i \in I}$, the expression $(q_1 \equiv_J q_2)$ abbreviates $(\forall j \in J : q_1 \equiv_j q_2)$.

Theorem 4. [CMT99,Muk02] *Let $(\Sigma, \text{Proc}, \Delta)$ be a distribution and $TS = (Q, \Sigma, \rightarrow, I)^2$ be a transition system. Then, TS is isomorphic to a synchronous product of transition systems over Δ if and only if for each $p \in \text{Proc}$ there exists an equivalence relation $\equiv_p \subseteq Q \times Q$ such that the following conditions hold:*

SP₁ : *If $q_1 \xrightarrow{a} q_2$, then $q_1 \equiv_{\text{Proc} \setminus \text{dom}(a)} q_2$.*

SP₂ : *If $q_1 \equiv_{\text{Proc}} q_2$, then $q_1 = q_2$.*

SP₃ : *Let $a \in \Sigma$ and $q \in Q$. If for each $p \in \text{dom}(a)$, there exist $q_p, q'_p \in Q$ such that $q_p \xrightarrow{a} q'_p$ and $q \equiv_p q_p$, then for each choice of such q_p 's and q'_p 's, there exists $q' \in Q$ such that $q \xrightarrow{a} q'$ and $q' \equiv_p q'_p$ for each $p \in \text{dom}(a)$.*

Theorem 5. *The implementability problem for synchronous products modulo isomorphism is NP-complete, even for acyclic specifications.*

Proof. First, it is easy to see that the problem is in NP: Given a distribution $(\Sigma, \text{Proc}, \Delta)$ and a transition system TS , a nondeterministic machine can ‘guess’ a family of equivalences $(\equiv_p)_{p \in \text{Proc}}$ and then verify in *polynomial* time (in the size of the distribution and of the transition system), whether the properties SP₁–SP₃ from Theorem 4 are satisfied or not.

For the NP-hardness part, we use a polynomial reduction from the classical SAT problem. Before going into details, we present an overview of the construction: Given a formula in conjunctive normal form, we associate to each variable and each clause, a group of three states and two transitions (as in Fig. 1). The nondeterminism is used to implement a choice gadget between the Boolean values **True** and **False** for each variable. We connect then the triples according to the occurrence of variables as literals in the clauses (these edges will be the wires that will transmit the information from variables to clauses). The distribution is

²In [CMT99,Muk02], Th. 4 is restricted to the case when $|I| = 1$. By inspecting the proof of [CMT99], it is easy to see that the theorem holds in fact for an arbitrary I .

chosen such that a clause will evaluate to **False** if and only if the condition SP_3 will be violated for the triple associated to the given clause. The application of Theorem 4 finishes the job.

Let ϕ be a formula in conjunctive normal form with variables x_1, \dots, x_n appearing in the clauses c_1, \dots, c_m . For technical reasons and w.l.o.g., we assume that no clause contains some variable both as a positive and as a negative literal.

We will construct a distribution $(\Sigma_\phi, Proc_\phi, \Delta_\phi)$ and a (nondeterministic) transition system $TS_\phi = (Q_\phi, \Sigma_\phi, \rightarrow_\phi, I_\phi)$ such that: ϕ is satisfiable if and only if TS_ϕ is isomorphic to a synchronous product of transition systems over Δ_ϕ . To relieve a bit the notation, we will drop all ϕ indices.

First, the set of processes $Proc$ consists of two processes for each variable and one process for each clause:

$$Proc := \{p_{x_i}, p_{\bar{x}_i} \mid i \in [1..n]\} \cup \{p_{c_j} \mid j \in [1..m]\}.$$

Then, the set Σ of actions and their domains (which determine Δ) consist of:

- one action for each variable: $\{a_{x_i} \mid i \in [1..n]\}$ with $dom(a_{x_i}) := \{p_{x_i}, p_{\bar{x}_i}\}$.
- two actions for each positive literal from each clause: $\{a_{x_i c_j}, a'_{x_i c_j} \mid j \in [1..m], x_i \in c_j\}$ with $dom(a_{x_i c_j}) = dom(a'_{x_i c_j}) := Proc \setminus \{p_{x_i}\}$.
- two actions for each negative literal from each clause: $\{a_{\bar{x}_i c_j}, a'_{\bar{x}_i c_j} \mid j \in [1..m], \bar{x}_i \in c_j\}$ with $dom(a_{\bar{x}_i c_j}) = dom(a'_{\bar{x}_i c_j}) := Proc \setminus \{p_{\bar{x}_i}\}$.
- two actions for each clause: $\{a_{c_j}, a'_{c_j} \mid j \in [1..m]\}$ with $dom(a_{c_j}) := \{p_{c_j}\} \cup \{p_{x_i} \mid x_i \in c_j\} \cup \{p_{\bar{x}_i} \mid \bar{x}_i \in c_j\}$ (the domain of a_{c_j} consists of the process associated to c_j and the processes associated to the literals of c_j) and $dom(a'_{c_j}) := Proc \setminus \{p_{c_j}\}$.

Last, we construct the transition system TS . The state space Q consists of:

- three states for each variable: $\{q_{x_i}^0, q_{x_i}, q'_{x_i} \mid i \in [1..n]\}$ and
- three states for each clause: $\{q_{c_j}, q'_{c_j}, q_{c_j}^0 \mid j \in [1..m]\}$.

The transition relation $\rightarrow \subseteq Q \times \Sigma \times Q$ is defined as follows:

- for each $i \in [1..n]$: $q_{x_i}^0 \xrightarrow{a_{x_i}} q_{x_i}$ and $q_{x_i}^0 \xrightarrow{a_{x_i}} q'_{x_i}$ (nondeterminism is allowed).
- for each $j \in [1..m]$: $q_{c_j} \xrightarrow{a_{x_i c_j}} q_{x_i}$ for $x_i \in c_j$, $q_{c_j} \xrightarrow{a_{\bar{x}_i c_j}} q_{x_i}$ for $\bar{x}_i \in c_j$, and $q_{c_j} \xrightarrow{a_{c_j}} q_{c_j}^0$.
- for each $j \in [1..m]$: $q'_{c_j} \xrightarrow{a'_{x_i c_j}} q'_{x_i}$ for $x_i \in c_j$, $q'_{c_j} \xrightarrow{a'_{\bar{x}_i c_j}} q'_{x_i}$ for $\bar{x}_i \in c_j$, and $q'_{c_j} \xrightarrow{a'_{c_j}} q_{c_j}$.

The set of initial states I is chosen such that all states of Q are reachable from I . For instance, $I := \{q_{x_i}^0 \mid i \in [1..n]\} \cup \{q'_{c_j} \mid j \in [1..m]\}$.³

An example is provided in Fig. 1 (the initial states are not marked).

³It is easy to modify the construction such that there is only *one initial state*.

Fig. 1. The transition system TS associated to $\phi = (x_1 \vee x_2) \wedge (\overline{x_2} \vee \overline{x_3})$

The ‘choice gadget’ is provided by the three states for each variable x_i and their associated transitions. The Boolean ‘value’ of each choice (this will be a local equivalence relation: either $q_{x_i} \equiv_{p_{x_i}} q'_{x_i}$ or $q_{x_i} \equiv_{p_{\overline{x_i}}} q'_{x_i}$) is then propagated further to the clauses using the transitions labeled $a_{x_i c_j}$ and $a_{\overline{x_i} c_j}$, respectively. More precisely, to each clause we forward only the information that a variable was set to **False** in such a way that the clause c_j is not satisfied iff q_{c_j} and q'_{c_j} are equivalent on all processes of the domain of a_{c_j} . Thus, a clause c_j will have all the literals evaluated to **False** if and only if the condition SP_3 will be violated for $a := a_{c_j}$, $q := q'_{c_j}$, and $q_p := q_{c_j}$, $q'_p := q'_{c_j}$ for all $p \in \text{dom}(a_{c_j})$.

The above construction is polynomial in the size of the initial formula ϕ and we claim that ϕ is satisfiable if and only if TS is isomorphic to a synchronous product of transition systems over Δ (given by dom).

First Implication. We first prove the easier part: ϕ is not satisfiable implies TS is not isomorphic to a synchronous product of transition systems over Δ . If ϕ is not satisfiable, then for any assignment of the variables x_1, \dots, x_n there exists a clause that is evaluated to **False**. We must show that in this case, there are no $(\equiv_p)_{p \in \text{Proc}}$ satisfying all SP_1 – SP_3 .

By contradiction, assume that there exist $(\equiv_p)_{p \in \text{Proc}}$ satisfying all SP_1 – SP_3 . For each $i \in [1..n]$, we use first the condition SP_3 which we have assumed to hold. Let $a := a_{x_i}$ and $q := q_{x_i}^0$. We choose $q_p \xrightarrow{a} q'_p$ from SP_3 for each $p \in \text{dom}(a_{x_i}) = \{p_{x_i}, p_{\overline{x_i}}\}$ as follows: $q_{x_i}^0 \xrightarrow{a_{x_i}} q_{x_i}$ for $p = p_{x_i}$ and $q_{x_i}^0 \xrightarrow{a_{x_i}} q'_{x_i}$ for $p = p_{\overline{x_i}}$. Since $q \equiv_{p_{x_i}} q_{x_i}^0$ and $q \equiv_{p_{\overline{x_i}}} q_{x_i}^0$ (recall that $q = q_{x_i}^0$), the hypothesis of SP_3 is satisfied, so there must exist a state q' such that $q_{x_i}^0 \xrightarrow{a_{x_i}} q'$, and also $q' \equiv_{p_{x_i}} q_{x_i}$ and $q' \equiv_{p_{\overline{x_i}}} q'_{x_i}$.

There are only two possible cases:

1. $q' = q_{x_i}$. In this case, we have $q_{x_i} \equiv_{p_{x_i}} q_{x_i}$ and $q_{x_i} \equiv_{p_{\overline{x_i}}} q'_{x_i}$.
2. $q' = q'_{x_i}$. In this case, we have $q'_{x_i} \equiv_{p_{x_i}} q_{x_i}$ and $q'_{x_i} \equiv_{p_{\overline{x_i}}} q'_{x_i}$.

So, we have that either $q_{x_i} \equiv_{p_{\overline{x_i}}} q'_{x_i}$ (case 1) or $q_{x_i} \equiv_{p_{x_i}} q'_{x_i}$ (case 2), but *not both at the same time* (otherwise, on one hand we have that $q_{x_i} \equiv_{\text{dom}(a_{x_i})} q'_{x_i}$

and on the other hand, by SP_1 applied to the transitions $q_{x_i} \xleftarrow{a_{x_i}} q_{x_i}^0 \xrightarrow{a_{x_i}} q'_{x_i}$, we have $q_{x_i} \equiv_{Proc \setminus dom(a_{x_i})} q'_{x_i}$, so $q_{x_i} \equiv_{Proc} q'_{x_i}$ which contradicts SP_2 .

Let us choose an assignment of the variables given by the equivalences in the following way. For each $i \in [1..n]$:

x_i is evaluated to **False** if and only if $q_{x_i} \equiv_{p_{x_i}} q'_{x_i}$.

Since ϕ is not satisfiable, there exists a clause, say c_k , that has all its literals evaluated to **False**. Let x_i be a positive literal in c_k (if any). Since the literal x_i is evaluated to **False**, we have that the variable x_i is **False**, so $q_{x_i} \equiv_{p_{x_i}} q'_{x_i}$. In

addition, we have $q_{c_k} \xrightarrow{a_{x_i c_k}} q_{x_i}$ and $q'_{c_k} \xrightarrow{a'_{x_i c_k}} q'_{x_i}$ (see the construction of TS) and, using SP_1 , we deduce that $q_{c_k} \equiv_{p_{x_i}} q_{x_i}$ and $q'_{c_k} \equiv_{p_{x_i}} q'_{x_i}$. By the transitivity of $\equiv_{p_{x_i}}$, we obtain that $q_{c_k} \equiv_{p_{x_i}} q'_{c_k}$. A similar argument for the negative literals \bar{x}_i in c_k (if any) proves that $q_{c_k} \equiv_{p_{\bar{x}_i}} q'_{c_k}$ ($q_{x_i} \equiv_{p_{\bar{x}_i}} q'_{x_i}$ is used). Moreover, using

SP_1 for $q'_{c_k} \xrightarrow{a'_{c_k}} q_{c_k}$, we have that $q_{c_k} \equiv_{p_{c_k}} q'_{c_k}$.

Summing up, we proved that $q'_{c_k} \equiv_p q_{c_k}$, for each $p \in dom(a_{c_k})$ (recall the definition of $dom(a_{c_k})$). But this contradicts SP_3 , because $q_{c_k} \xrightarrow{a_{c_k}} q_{c_k}^0$ and there is no state q' such that $q'_{c_k} \xrightarrow{a_{c_k}} q'$.

Second Implication. We move now to the second part of the proof, assuming that ϕ is satisfiable. Then, there exists an assignment to the variables x_1, \dots, x_n such that each clause is **True**. We prove that TS is isomorphic to a synchronous product of transition systems over $(\Sigma, Proc, \Delta)$. For that, we construct a family of equivalences $(\equiv_p)_{p \in Proc}$ in the following way:

Step 0 For each $p \in Proc$, initialize the binary relation $\equiv_p \subseteq Q \times Q$ to \emptyset .

Step 1 For each $q \xrightarrow{a} q'$, choose $q \equiv_p q'$ for each $p \in Proc \setminus dom(a)$.

Step 2 For each $i \in [1..n]$, if variable x_i is evaluated to **False**, then choose $q_{x_i} \equiv_{p_{x_i}} q'_{x_i}$, otherwise choose $q_{x_i} \equiv_{p_{\bar{x}_i}} q'_{x_i}$.

Step 3 For each $p \in Proc$, close \equiv_p under reflexivity, symmetry, and transitivity.

Table 3 describes the equivalence classes of our equivalences generated above. Each cell gives the partition of the state space Q into the equivalence classes for each type of process (rows) depending on the value of the associated variable (columns). Each equivalence class is given as a set in curly brackets. It is tedious, but not hard to check the correctness of Table 3 (i.e., the equivalence classes presented are the ones generated by the Steps 0–3 above). Based on it, we prove that the chosen $(\equiv_p)_{p \in Proc}$ satisfy SP_3 , SP_2 , and SP_1 (in this order):

Remark 6. ⁴ SP_3 holds for action $a := a_{x_i}$, for each $i \in [1..n]$.

Note that each action $a \in \Sigma \setminus \{a_{x_i} \mid i \in [1..n]\}$ has the property that there exists *only one* transition labeled with a in the transition system TS . In this case, the condition SP_3 can be simplified as below:

⁴The proof can be found in the Appendix A.1.

Table 3. The equivalence classes constructed in the 2nd part of the proof of Th. 5

	$x_i = \text{False}$	$x_i = \text{True}$
$\equiv_{p_{x_i}}$	$\{q_{x_i}^0\}, \{q_{x_{i'}}, q_{x_{i'}}, q'_{x_{i'}}\}$ for each $i' \neq i$, $\{q_{x_i}, q'_{x_i}\} \cup \{q_{c_j}, q'_{c_j} \mid x_i \in c_j\}$, $\{q_{c_j}^0\}$ for each c_j containing lit. x_i , and $\{q_{c_{j'}}, q_{c_{j'}}^0\}, \{q'_{c_{j'}}\}$ for each $c_{j'}$ not containing the positive literal x_i	$\{q_{x_i}^0\}, \{q_{x_{i'}}, q_{x_{i'}}, q'_{x_{i'}}\}$ for each $i' \neq i$, $\{q_{x_i}\} \cup \{q_{c_j} \mid x_i \in c_j\}$, $\{q'_{x_i}\} \cup \{q'_{c_j} \mid x_i \in c_j\}$, $\{q_{c_j}^0\}$ for each c_j containing lit. x_i , and $\{q_{c_{j'}}, q_{c_{j'}}^0\}, \{q'_{c_{j'}}\}$ for each $c_{j'}$ not containing the positive literal x_i
$\equiv_{p_{\bar{x}_i}}$	$\{q_{x_i}^0\}, \{q_{x_{i'}}, q_{x_{i'}}, q'_{x_{i'}}\}$ for each $i' \neq i$, $\{q_{x_i}\} \cup \{q_{c_j} \mid \bar{x}_i \in c_j\}$, $\{q'_{x_i}\} \cup \{q'_{c_j} \mid \bar{x}_i \in c_j\}$, $\{q_{c_j}^0\}$ for each c_j containing lit. \bar{x}_i , and $\{q_{c_{j'}}, q_{c_{j'}}^0\}, \{q'_{c_{j'}}\}$ for each $c_{j'}$ not containing the negative literal \bar{x}_i	$\{q_{x_i}^0\}, \{q_{x_{i'}}, q_{x_{i'}}, q'_{x_{i'}}\}$ for each $i' \neq i$, $\{q_{x_i}, q'_{x_i}\} \cup \{q_{c_j}, q'_{c_j} \mid \bar{x}_i \in c_j\}$, $\{q_{c_j}^0\}$ for each c_j containing lit. \bar{x}_i , and $\{q_{c_{j'}}, q_{c_{j'}}^0\}, \{q'_{c_{j'}}\}$ for each $c_{j'}$ not containing the negative literal \bar{x}_i
$\equiv_{p_{c_j}}$	$\{q_{x_i}^0, q_{x_i}, q'_{x_i}\}$ for $i \in [1..n]$, $\{q_{c_j}, q'_{c_j}\}, \{q_{c_j}^0\}$, and $\{q_{c_{j'}}, q_{c_{j'}}^0\}, \{q'_{c_{j'}}\}$ for $j' \neq j$	

Table 4. Details for the satisfaction of the SP_3 property

a	q	Why SP_3 holds (a process p from $\text{dom}(a)$ is given)
a_{x_i}		See Remark 6.
$a_{x_i c_j}$ (for $x_i \in c_j$)	$\{q_{c_j}^0\}$ $Q \setminus \{q_{c_j}, q_{c_j}^0\}$	$p := p_{c_j}$. Indeed, $q_{c_j} \not\equiv_{p_{c_j}} q_{c_j}^0$. $p := p_{\bar{x}_i}$. Indeed, $x_i \in c_j$ implies $\bar{x}_i \notin c_j$ (see construction of ϕ), so $q_{c_j} \not\equiv_{p_{\bar{x}_i}} q, \forall q \in Q \setminus \{q_{c_j}, q_{c_j}^0\}$.
$a'_{x_i c_j}$ (for $x_i \in c_j$)	$Q \setminus \{q'_{c_j}\}$	$p := p_{\bar{x}_i}$. Same as above, $x_i \in c_j$ implies $\bar{x}_i \notin c_j$ and in this case $q'_{c_j} \not\equiv_{p_{\bar{x}_i}} q, \forall q \in Q \setminus \{q'_{c_j}\}$.
$a_{\bar{x}_i c_j}, a'_{\bar{x}_i c_j}$ (for $\bar{x}_i \in c_j$)		Similar to the cases $a_{x_i c_j}, a'_{x_i c_j}$ above.
a_{c_j}	$\{q'_{c_j}\}$ $Q \setminus \{q_{c_j}, q'_{c_j}\}$	Since c_j evaluates to True , there exists a literal ℓ of c_j evaluated to True . Assume $\ell = x_i$, such that $x_i \in c_j$ and $x_i = \text{True}$ (a similar analysis is made if ℓ is negative). Then, for $p := p_{x_i}$ we have that $p_{x_i} \in \text{dom}(a_{c_j})$ and $q_{c_j} \not\equiv_{p_{x_i}} q'_{c_j}$. $p := p_{c_j}$. Indeed, $q_{c_j} \not\equiv_{p_{c_j}} q, \forall q \in Q \setminus \{q_{c_j}, q'_{c_j}\}$.
a'_{c_j}	$Q \setminus \{q'_{c_j}\}$	For a given variable x_i , the literals x_i and \bar{x}_i cannot appear both in c_j . If $x_i \notin c_j$, then $p := p_{x_i}$ (and indeed, $q'_{c_j} \not\equiv_{p_{x_i}} q, \forall q \in Q \setminus \{q'_{c_j}\}$). If $\bar{x}_i \notin c_j$, then $p := p_{\bar{x}_i}$.

Table 5. Details for the SP_2 property (only cases not solved already by Table 4)

q_1	q_2	Why SP_2 holds (a process p from Proc is given)
$q_{x_i}^0$	$Q' \setminus \{q_{x_i}^0\}$	$p := p_{x_i}$. Indeed, $q_{x_i}^0 \not\equiv_{p_{x_i}} q, \forall q \in Q' \setminus \{q_{x_i}^0\}$.
q_{x_i}	$\{q_{x_i}^0, q'_{x_i}\}$ $Q' \setminus \{q_{x_i}, q_{x_i}, q'_{x_i}\}$	If x_i is True then $p := p_{x_i}$ else $p := p_{\bar{x}_i}$. $p := p_{c_j}$ for an arbitrary $j \in [1..m]$.
q'_{x_i}		Similar to the case q_{x_i} above.
$q_{c_j}^0$	$Q' \setminus \{q_{c_j}^0\}$	$p := p_{c_j}$.

Remark 7. ⁴ Let $a \in \Sigma$ such that there is only one transition, say $q_a \xrightarrow{a} q'_a$, labeled with a in TS . Then, SP_3 holds for the chosen a if and only if for each state $q \neq q_a$, there exists a process $p \in \text{dom}(a)$ such that $q \not\equiv_p q_a$.

Since Remark 6 shows that SP_3 holds for $a \in \{a_{x_i} \mid i \in [1..n]\}$, the remaining cases are solved in Table 4 using Remark 7. The first column picks a value for a , while the second one gives a range to the state $q \in Q \setminus \{q_a\}$ from the formulation of Remark 7. In the last column, we give a process $p \in \text{dom}(a)$ such that $q_a \not\equiv_p q$, for all q in the range given by second column. The correctness of the solutions provided is verified using the equivalence classes given in Table 3.

Remark 8. SP_2 holds iff for each $q_1 \neq q_2$, there exists $p \in \text{Proc}$ with $q_1 \not\equiv_p q_2$.

Table 5 presents only the cases for which Table 4 did not give a process to ‘distinguish’ two different states q_1 (column 1) and q_2 (in the range given in column 2), i.e., we give a process $p \in \text{Proc}$ such that $q_1 \not\equiv_p q_2$. More precisely, we only have to consider pairs of states from the subset:

$$Q' := \{q_{x_i}^0, q_{x_i}, q'_{x_i} \mid i \in [1..n]\} \cup \{q_{c_j}^0 \mid j \in [1..m]\}.$$

Condition SP_1 is fulfilled by construction (Step 1). □

Going into the proof details of Theorem 4 given in [CMT99], we can show that if there exist a set of equivalences $(\equiv_p)_{p \in \text{Proc}}$ satisfying only conditions SP_1 and SP_3 (but not necessarily SP_2), then we can synthesize a synchronous product of transition systems accepting the same language as the initial transition system.⁵ This trick widens the class of ‘implementable’ transition systems, while preserving the behavior. Yet, the problem is as hard as the implementability modulo isomorphism (from which we do the reduction – see the proof in the Appendix A.2):

Corollary 9. *Let $(\Sigma, \text{Proc}, \Delta)$ be a distribution and TS a transition system. The problem of finding a set of equivalences $(\equiv_p)_{p \in \text{Proc}}$ satisfying only conditions SP_1 and SP_3 of Theorem 4, is NP-complete.*

Proposition 10. *[Mor98] The implementability problem for synchronous products modulo isomorphism becomes decidable in polynomial time, if the input transition system is deterministic.*

3.2 Asynchronous Automata

Similar results to those for synchronous products of transition systems hold for asynchronous automata. The NP-completeness proof of Theorem 12 has a similar structure to the proof of Theorem 5, but the details are different. The proof can be found in the Appendix A.3.

⁵In fact, the synthesized synchronous product is even bisimilar (in the sense of Milner) to the initial transition system.

Theorem 11. [Mor99,Muk02] Let $(\Sigma, Proc, \Delta)$ be a distribution and $TS = (Q, \Sigma, \rightarrow, I)$ be a transition system. Then, TS is isomorphic to an asynchronous automaton over Δ if and only if for each $p \in Proc$ there exists an equivalence relation $\equiv_p \subseteq Q \times Q$ such that the following conditions hold:

- AA₁ : If $q_1 \xrightarrow{a} q_2$, then $q_1 \equiv_{Proc \setminus dom(a)} q_2$.
 AA₂ : If $q_1 \equiv_{Proc} q_2$, then $q_1 = q_2$.
 AA₃ : If $q_1 \xrightarrow{a} q'_1$ and $q_1 \equiv_{dom(a)} q_2$, then there exists q'_2 such that $q_2 \xrightarrow{a} q'_2$ and $q'_1 \equiv_{dom(a)} q'_2$.

Theorem 12. The implementability problem for asynchronous automata modulo isomorphism is NP-complete, even for acyclic specifications.

Corollary 13. Let $(\Sigma, Proc, \Delta)$ be a distribution and TS a transition system. The problem of finding a set of equivalences $(\equiv_p)_{p \in Proc}$ satisfying only conditions AA₁ and AA₃ of Theorem 11, is NP-complete.

Proposition 14. [Mor98] The implementability problem for asynchronous automata modulo isomorphism becomes decidable in polynomial time, if the input transition system is deterministic.

4 Implementability modulo Language Equivalence

This section presents the complexity of checking whether an input transition system admits the same sequences of actions as a distributed transition system.

A run of a transition system TS is a sequence of labels $a_1 \dots a_n \in \Sigma^*$ such that: $\exists q^{in} \in I, q \in Q : q^{in} \xrightarrow{a_1} \dots \xrightarrow{a_n} q$ (also written as $q^{in} \xrightarrow{a_1 \dots a_n} q$). The language of TS is the set of all its runs, $L(TS) := \{w \in \Sigma^* \mid \exists q^{in} \in I, q \in Q, q^{in} \xrightarrow{w} q\}$. Note that the language of a transition system is prefix-closed, i.e., $\forall u, w \in \Sigma^* : uw \in L \Rightarrow u \in L$. In fact, we have:

Lemma 15. A language $L \subseteq \Sigma^*$ is accepted by a finite transition system if and only if L is a prefix-closed regular language.

The language of a distributed transition system is defined to be the language of its underlying global transition system.

4.1 Synchronous Products of Transition Systems

The synthesis modulo language equivalence for synchronous products is based on projections onto the local alphabets of the distribution. The solution provided in [Muk02] works only for the class of synchronous products with just one initial state ($|I| = 1$ in Def. 1). In this section we discuss only the complexity of this problem and we will touch upon the general case at the end of the next section.

Problem 16. Given a distribution $(\Sigma, Proc, \Delta)$ and a finite transition system TS , does there exist a synchronous product of transition systems over Δ with only one initial state that is language equivalent to TS ?

We present, following [Muk02], the algorithm of deciding Problem 16:
Let $(\Sigma, Proc, \Delta)$ be a distribution and TS a transition system:

1. W.l.o.g. we suppose that TS has only one initial state.
2. Let $TS = (Q, \Sigma, \rightarrow, \{q^{in}\})$. For each process $p \in Proc$, we construct a projection $TS_p := (Q, \Sigma_{loc}(p), \rightarrow_p, \{q^{in}\})$ obtained from a copy of TS in which the labels from $\Sigma \setminus \Sigma_{loc}(p)$ are replaced by ε and \rightarrow_p is the ε -closure of \rightarrow (a polynomial algorithm for ε -closure can be found in [HU79, Chap. 2.4]).
3. Problem 16 has a positive answer iff TS is language equivalent to the synchronous product over Δ of the transition systems $(TS_p)_{p \in Proc}$ with one global initial state (q^{in}, \dots, q^{in}) .

We introduce now the reachability problem used in a subsequent reduction:

Problem 17. (Reachability in synchronous products) Given $(\Sigma, Proc, \Delta)$ a distribution, a set of local transition systems $(TS_p)_{p \in Proc}$ with $TS_p = (Q_p, \Sigma_{loc}(p), \rightarrow_p, \{q_p^{in}\})$, and a global state $q \in \prod_{p \in Proc} Q_p$, is the state q reachable from the global initial state $(q_p^{in})_{p \in Proc}$ via the global synchronization of \rightarrow_p 's as in Def. 1?

Lemma 18. *The non-reachability problem (i.e., the complement of Problem 17) for synchronous products can be in polynomial time reduced to Problem 16.*

Proof. Given a distribution $(\Sigma, Proc, \Delta)$, we suppose $Proc := \{1, \dots, n\}$. Also, we are given a local transition system $TS_p = (Q_p, \Sigma_{loc}(p), \rightarrow_p, \{q_p^{in}\})$ for each $p \in [1..n]$ and a global state $q \in \prod_{p \in Proc} Q_p$.

We construct a distribution $(\Sigma', Proc', \Delta')$ and a transition system R such that: Problem 16 has a solution for Δ' and R if and only if the global state $q := (q_1, \dots, q_n)$ is not reachable from the global initial state $(q_1^{in}, \dots, q_n^{in})$.

The new distribution $(\Sigma', Proc', \Delta')$ is chosen as follows:

- $\Sigma' := \Sigma \cup \{a_p \mid p \in [1..n]\} \cup \{\checkmark\}$. (Note that $\Sigma = \bigcup_{p \in [1..n]} \Sigma_{loc}(p)$.)
- $Proc' := Proc \cup \{p_0\}$, and
- $\Delta' \subseteq \Sigma' \times Proc'$ is given by the local alphabets $\Sigma'_{loc}(p)$ as:
 - $\Sigma'_{loc}(p) := \Sigma_{loc}(p) \cup \{a_{p'} \mid p' \in [1..n] \wedge p' \neq p\} \cup \{\checkmark\}$ for $p \in [1..n]$ and
 - $\Sigma'_{loc}(p_0) := \Sigma' \setminus \{\checkmark\}$.

This gives the following domains dom' for the actions of Σ' :

- $dom'(a) = dom(a) \cup \{p_0\}$, for all $a \in \Sigma$ (where $dom(a)$ is given by Δ),
- $dom'(a_p) = Proc' \setminus \{p\}$, for all $p \in [1..n]$, and
- $dom'(\checkmark) = Proc' \setminus \{p_0\} = Proc$.

The transition system $R := (Q', \Sigma', \rightarrow, \{q_0\})$ is sketched in Fig. 2 and defined as:

- $Q' := \{q_0, q'_0\} \cup \bigcup_{p \in [1..n]} Q_p \cup \{q'_p \mid p \in [1..n]\}$ (with $Q_p \cap Q_{p'} = \emptyset$ for $p \neq p'$),
- $\rightarrow := \{q_0 \xrightarrow{a} q'_0 \mid a \in \Sigma\} \cup \{q'_0 \xrightarrow{a} q'_0 \mid a \in \Sigma\} \cup \bigcup_{p \in [1..n]} \left(\{q_0 \xrightarrow{a_p} q_p^{in}\} \cup \rightarrow_p \cup \{q_p \xrightarrow{\checkmark} q'_p\} \right)$.

Fig. 2. A schematic representation of the reduction in Lemma 18

Remark 19. According to Step 2 in the decision algorithm for Problem 16, we reconstruct the projections R_p of R onto the local alphabets $\Sigma'_{loc}(p)$ as follows: For $p \in [1..n]$, R_p is obtained from R replacing the labels from $\Sigma' \setminus \Sigma'_{loc}(p)$ by ε and applying an ε -closure. Since $a_p \notin \Sigma'_{loc}(p)$ and $\Sigma_{loc}(p) \cup \{\sqrt{\}\} \subseteq \Sigma'_{loc}(p)$, we have that all the states reachable by a run v from q_p^{in} in TS_p can also be reached by the same run v from q_0 in R_p . For $p := p_0$, since $\Sigma'_{loc}(p_0) = \Sigma' \setminus \{\sqrt{\}\}$, the projection R_{p_0} is just R without the $\sqrt{\}$ -labeled transitions.

First Implication. We assume that R is implementable over Δ' and we prove that the global state $q := (q_1, \dots, q_n)$ is not reachable from $q^{in} := (q_1^{in}, \dots, q_n^{in})$ in the synchronous product of the TS_p 's over Δ .

By contradiction, suppose that there exists a run $w \in \Sigma^*$ such that q is reachable from q^{in} after executing the sequence w of actions. We show that R is not language equivalent to the synchronous product over Δ' of its projections R_p as described in the decision algorithm for Problem 16:

On one hand, the run $w\sqrt{\} \notin L(R)$ because all the runs of R containing $\sqrt{\}$ start with an a_p action and $a_p \notin \Sigma$, for any $p \in [1..n]$.

On the other hand, we can show that $w\sqrt{\}$ is a run of the synchronization of the R_p 's. Informally, we will simulate the synchronizations of TS_p 's on $w \in \Sigma^*$ by synchronizations of R_p 's and at the end we will also have a synchronization of the local transitions $q_p \xrightarrow{\sqrt{\}} q'_p$:

In the synchronous product of the TS_p 's, we can execute w from q^{in} and we reach q . According to Def. 1, the synchronization on each $a \in \Sigma$ involves only the processes of $dom(a)$. When synchronizing the projections R_p on $a \in \Sigma$, we must observe $dom'(a) = dom(a) \cup \{p_0\}$. For $p := p_0$, we can always execute $a \in \Sigma$ from $q_0 \xrightarrow{a} q'_0 \xrightarrow{a} q'_0$ which is part of R_{p_0} . For $p \in dom(a)$, we can move in R_p (starting in q_0) similar to the synchronization of the TS_p (starting in q_0^{in}) according to Remark 19. In this way, we are able to execute w in the synchronous product of the R_p starting from the global state (q_0, \dots, q_0) and to reach the state q_p in R_p for each $p \in [1..n]$. Since $dom'(\sqrt{\}) = Proc = [1..n]$ and we have $q_p \xrightarrow{\sqrt{\}} q'_p$ in each $p \in [1..n]$, we can finally have a $\sqrt{\}$ -synchronization. Therefore, the run $w\sqrt{\}$ belongs to the synchronization of the R_p 's over Δ' .

Second Implication. We assume that q is not reachable from q^{in} in the synchronization of the TS_p 's, and we prove that R is language equivalent to the synchronization of its projections over Δ' . Since it is easy to show that in general the

language of a transition system is included in the language of the synchronization of its projections, we only have to prove the reverse inclusion.

Let $v \in \Sigma'$ be a run of the synchronization of the R_p 's. We will show that $v \in L(R)$. It is easy to see that v can only have two forms:

$v \in (\Sigma' \setminus \{\checkmark\})^*$: From $\Sigma'_{loc}(p_0) = \Sigma' \setminus \{\checkmark\}$, we necessarily have that $v \in L(R_{p_0})$. Then, with the help of Remark 19, $L(R_{p_0}) \subseteq L(R)$, so $v \in L(R)$.

$v = w\checkmark$ with $w \in (\Sigma' \setminus \{\checkmark\})^*$: Again, from $\Sigma'_{loc}(p_0) = \Sigma' \setminus \{\checkmark\}$, we necessarily have that $w \in L(R_{p_0})$. Looking at R_{p_0} , w can only have two forms:

$w \in \Sigma^*$: We show that this is not possible, given the fact that $w\checkmark$ is a run of the synchronization of the R_p 's. The action \checkmark will be executed only if all R_p 's with $p \in \text{dom}'(\checkmark) = [1..n]$ will execute a \checkmark -labeled transition and this implies that no R_p with $p \in [1..n]$ will ever synchronize on a $q_0 \xrightarrow{a} q'_0$ transition for $a \in \Sigma$, because no run from q'_0 can contain \checkmark . That means that the synchronization of the R_p 's on $w \in \Sigma^*$ simulates a synchronization of the TS_p 's on w . From the hypothesis, $q = (q_1, \dots, q_n)$ is not reachable, so no \checkmark -synchronization will be possible.

$w = a_i u$ with $i \in [1..n]$ and $u \in L(TS_i)$: Since the first action of w (and v) is a_i and $\text{dom}'(a_i) = \text{Proc}' \setminus \{i\}$, all R_p 's *except* R_i must execute their local $q_0 \xrightarrow{a_i} q_p^{in}$ transition (this transition belongs to R_p for $p \neq i$, because in this case $a_i \in \Sigma'_{loc}(p)$). Then, the R_p 's must synchronize on u such that at the end also a \checkmark -synchronization is possible. Since $u \in L(TS_i)$, we have that $u \in (\Sigma'_{loc}(i))^*$ and also $u\checkmark \in (\Sigma'_{loc}(i))^*$. That means that R_i will take part in all synchronizations on $u\checkmark$ starting from q_0 and the only possibility for R_i to do this is by $q_0 \xrightarrow{u} q_i \xrightarrow{\checkmark} q'_i$. This necessarily implies a run $q_i^{in} \xrightarrow{u} q_i$ in TS_i (because $\Sigma_{loc}(i) \subseteq \Sigma'_{loc}(i)$), which further implies a run $q_0 \xrightarrow{a_i} q_i^{in} \xrightarrow{u} q_i \xrightarrow{\checkmark} q'_i$ in R , so $v \in L(R)$. \square

The next results are based on the complexity results for checking non-reachability and language equivalence of synchronous products from [SHRS96]:

Theorem 20. *The implementability problem for synchronous products with $|I| = 1$ modulo language equivalence is PSPACE-complete.*

Proof. The PSPACE-hardness follows from Lemma 18 and the PSPACE-hardness of the non-reachability problem for synchronous products [SHRS96, Th. 3.10].

According to Step 3 of the decision algorithm of our problem, it is enough to check whether TS is language equivalent to the synchronization of its projections TS_p . But this test can be done in PSPACE as proved by [SHRS96, Th. 3.12]. \square

Proposition 21. *The implementability problem for synchronous products with $|I| = 1$ modulo language equivalence remains PSPACE-complete, when the input transition system TS is deterministic. For acyclic specifications the problem is coNP-complete, and it remains so even for deterministic ones.*

Proof. The PSPACE-hardness proof of [SHRS96, Th. 3.10] works in fact for *deterministic* TS_p 's. The reduction of Lemma 18 constructs a deterministic input transition system R if the components TS_p 's are all deterministic (see Fig. 2).

When TS is supposed to be acyclic, the coNP-hardness follows from the coNP-hardness of the non-reachability problem for synchronous products of *acyclic* and *deterministic* transition systems [SHRS96, Th. 3.16] and from Lemma 18 in which we modify the construction of R by replacing the loops $\{q'_0 \xrightarrow{a} q'_0 \mid a \in \Sigma\}$ by a set of new transitions $\bigcup_{j \in [0..M]} \{s_j \xrightarrow{a} s_{j+1} \mid a \in \Sigma\}$, where $s_0 = q'_0$ and $M = \max\{|w| \mid w \in L(TS_p), p \in [1..n]\}$ (this maximum exists if all the TS_p 's are acyclic). In this way R is acyclic if all the TS_p 's are acyclic and the reduction is still correct. The coNP-completeness follows from [SHRS96, Th. 3.17], which easily proves that checking language equivalence of synchronous products of acyclic transition systems is in coNP. \square

4.2 Asynchronous Automata

The ‘engine’ of the synthesis modulo language equivalence for asynchronous automata is a classical result by Zielonka [Zie87] which constructs a (deterministic) asynchronous automaton accepting a regular *trace* language.

We go now a bit more into details. Each distribution $(\Sigma, Proc, \Delta)$ generates an *independence* relation between the actions of Σ : $a \parallel b$ iff $dom(a) \cap dom(b) = \emptyset$. Then, we say $T \subseteq \Sigma^*$ is a *trace language* if T is closed under the independence relation: $\forall w, w' \in \Sigma^*, a, b \in \Sigma : wabw' \in T \wedge a \parallel b \Rightarrow wbaw' \in T$. According to [Zie87], for any regular trace language T there exists an asynchronous automaton equipped with a set of global accepting states recognizing T . Zielonka devoted a subsequent paper [Zie89] to obtain the same result for the restricted class of *safe* asynchronous automata which have the property that any run from an initial state can be extended to an accepted run.⁶ Global accepting states are not really suitable for a distributed setting and for this reason we defined in this paper the language of an asynchronous automaton as the set of *all* possible runs from an initial state. Using [Zie89] we easily get the following characterization (see proof in the Appendix A.4):

Proposition 22. *A language $T \subseteq \Sigma^*$ is accepted by an asynchronous automaton if and only if T is a prefix-closed regular trace language.*

Theorem 23. *The implementability problem for asynchronous automata modulo language equivalence is PSPACE-complete.*

Proof. Our implementability problem is in PSPACE, due to Proposition 22 and [PWW98, Th. 8 with Cor. 10] which proved that checking whether the language of a finite automaton is a trace language can be decided in PSPACE.

For the PSPACE-hardness part, we use a simple reduction from the totality problem ‘ $= \Sigma^*$?’ for nondeterministic finite automata, which is known to be

⁶However, for a regular trace language, there exists a *deterministic* asynchronous automaton accepting it [Zie87], but not necessarily a deterministic safe one [Zie89].

Fig. 3. Schematic representations of the reductions in Th. 23 (left) and Prop. 24 (right)

PSPACE-hard [GJ79]. For each nondeterministic finite automaton \mathcal{A} over Σ , which we can suppose w.l.o.g. that has only one initial q^{in} , respectively only one accepting state q^{acc} , we build a transition system TS over $\Sigma \cup \{a, b, c\}$ as in Fig. 3 (left) and a distribution such that $b||c$ is the only independence. It is easy to prove that $L(\mathcal{A}, \{q^{acc}\}) = \Sigma^*$ iff $L(TS)$ is a trace language (this is enough according to Proposition 22). The details are given in the Appendix A.4. \square

Proposition 24. *The implementability problem for asynchronous automata modulo language equivalence for deterministic specifications is decidable in polynomial time. For acyclic specifications, the problem is coNP-complete.*

Proof. The first part follows directly from Proposition 22 and [PWW98, Th. 7] proving that it is decidable in polynomial time whether the language of a deterministic finite automaton is a trace language.

For the second part, we use a simple reduction sketched in Fig. 3 (right) from the NP-complete problem if two acyclic nondeterministic automata \mathcal{A}_1 and \mathcal{A}_2 accept different languages [GJ79]. The proof is similar to the proof of Theorem 23 and the details are given in the Appendix A.4. \square

Based on the observation that the language accepted by a synchronous product is necessarily a trace language, we can recycle the constructions in Fig. 3 to derive complexity bounds for synchronous products with multiple initial states. (The proof details are given in the Appendix A.4.)

Theorem 25. *The implementability problem for synchronous products of transition systems modulo language equivalence is PSPACE-hard. For acyclic specifications, the problem is coNP-complete.*

However, we suspect that the above general problem is much harder than PSPACE. Moreover, we do not know anything about its complexity when the specification is deterministic.

Non-regular Specifications The following result suggests that there is no hope to test the implementability once we move higher in Chomsky's hierarchy:

Proposition 26. *Checking that a context-free language is a trace language is undecidable.*

The proof (given in the Appendix A.4) uses the fact that the set of invalid computations of a Turing machine is a context-free language [HU79, Lemma 8.7], together with the trick of making the first two letters of an accepting computation independent (see the proof technique of [PWW98, Th. 11]). Given the fact that the language of any distributed system exhibiting independence of actions is a trace language, one could dare to interpret this result in a programming language framework as: The synthesis problem for distributed programs with (possibly recursive) *procedures* and variables over finite domains is undecidable.

5 Deterministic Implementability modulo Bisimulation

Based on the observation that bisimilarity and language equivalence coincide for deterministic transitions systems, [Muk02] provides characterizations for the synthesis modulo bisimulation with the restriction that *the distributed implementation is deterministic* (the specification may still be nondeterministic). More precisely, the deterministic implementability problem modulo bisimulation for a given input TS reduces to checking whether the quotient TS/\sim_{TS} (with \sim_{TS} the largest bisimulation on TS) is deterministic and then checking deterministic implementability modulo language equivalence. As a consequence, we can infer basically the same complexity results as for implementability with deterministic specifications from Propositions 21 and 24. Appendix A.5 gives the details.

However, the synthesis problem modulo bisimulation is still open in the case of nondeterministic implementations.

6 Prototype Implementations

Comparing the deterministic and nondeterministic assumptions, dealing with deterministic specifications/implementations has a computational advantage. Nevertheless, it is worth considering also the nondeterministic case: In case the original specification is given as a regular language, a nondeterministic transition system exhibiting the given behavior may be exponentially more succinct than a deterministic one with the same behavior. Moreover, the nondeterministic distributed systems that we considered are *strictly more expressive* than their deterministic counterparts as the simple example below shows:

Example 27. Let us choose the language $L = \{\varepsilon, a, b\}$ with the distribution $\Sigma := \{a, b\}$, $Proc := \{1, 2\}$, and $\Delta := \{(a, 1), (b, 2)\}$. L is accepted by a nondeterministic synchronous product, but not by a deterministic one and L is accepted by a nondeterministic asynchronous automaton, but not by a deterministic one.

Briefly, L is accepted by the nondeterministic transition system of Fig. 4 which is isomorphic to a synchronous product (using Th. 4). On the other hand, the only deterministic transition systems accepting L are given in Fig. 4, but none of them is isomorphic to a synchronous product (using again Th. 4). The same holds for asynchronous automata (using Th. 11).

Fig. 4. Transition systems for Example 27

In this section, we will present some prototype implementations intended to complement the tool SYNASYNC [SEM03] which synthesizes asynchronous automata from deterministic specifications.⁷ More precisely, we consider the NP-complete test provided by Theorem 11 (working for general transition systems) and use it as a heuristic for the synthesis of asynchronous automata. Moreover, we provide an alternative implementation for another NP-complete problem (namely, finding an implementable subautomaton) involved in SYNASYNC.

We used a constraint-based logic programming framework called SMOBELS (<http://www.tcs.hut.fi/Software/smodels/>). It consists of `smodels`, an efficient implementation of the stable model semantics for normal logic programs, and `lparse`, a grounder front-end that transforms normal logic programs (with variables) to ground logic programs (without variables). We translate the synthesis problem into the problem of finding a stable model of a logic program. The program itself is written in the input syntax of `lparse`. The synthesis solutions (if any!) are given as stable models of the input program. A more detailed description of the SMOBELS system can be found in the `lparse 1.0 User's Manual` (<http://www.tcs.hut.fi/Software/smodels/lparse.ps>) and a general tutorial on the stable model semantics in [SNS02].

We chose to use logic programs with stable model semantics over the more widely used SAT for the main reason that in the stable model semantics the notion of a least fixpoint is trivial to express (we need this e.g. for the reachability property). However, in a SAT encoding we would have to encode the least fixpoint computation procedure itself (e.g. as a series of approximations) which would have resulted in additional blow-up of the translation not to mention implementation effort. An additional advantage of using SMOBELS is that the code is very concise. The actual implementation of synthesis without any optimizations has no more than 20 lines of code and it is given in the Appendix B.1.

The existing tools implementing the notion of regions for the synthesis of a distributed system (see SYNET [Cai97], PETRIFY [CKK⁺97], and SYNASYNC [SEM03]) do not handle nondeterministic specifications. In this sense, we can say that our implementation widens the class of systems tackled. Of course, one can always determinize the specification and the behavior is preserved, but then the tests of *isomorphism* to a distributed system are incomparable w.r.t. the two inputs because the *structure* is changed in the process of determinization.

⁷The implementation for synchronous products is left for future investigations.

Experience has shown that in most cases the initial specification is not isomorphic to the global state space of a distributed system (see, for example, [Cai97,SEM03,Yak98]). Several approaches to tackle this problem have been proposed (most of them are at least NP-hard and at the level of heuristics): label-splitting, introduction of silent events (both not really suitable for our framework⁸), changing the distribution, cutting transitions followed by unfolding. We opt for the last type of heuristics which proved fruitful in the experiments of [SEM03] in the context of asynchronous automata.

We introduce first some definitions needed in the presentation of the heuristic. Let $TS = (Q, \Sigma, \rightarrow, I)$ be a transition system. TS is *deadlock-free* if: $\forall q \in Q \exists a \in \Sigma, q' \in Q : q \xrightarrow{a} q'$. The set of actions *appearing* in TS is $\Sigma(TS) := \{a \in \Sigma \mid \exists q, q' \in Q : q \text{ reachable and } q \xrightarrow{a} q'\}$. Also, we say that $TS' = (Q', \Sigma, \rightarrow', I')$ is a *subautomaton* of TS if $Q' \subseteq Q, I' \subseteq I$, and $\rightarrow' \subseteq \rightarrow$. Finally, TS satisfies the *independent* and *forward diamond* rules if:

$$\mathbf{ID} : q_1 \xrightarrow{a} q_2 \xrightarrow{b} q_4 \wedge a \parallel b \Rightarrow \exists q_3 : q_1 \xrightarrow{b} q_3 \xrightarrow{a} q_4, \text{ and}$$

$$\mathbf{FD} : q_1 \xrightarrow{a} q_2 \wedge q_1 \xrightarrow{b} q_3 \wedge a \parallel b \Rightarrow \exists q_4 : q_2 \xrightarrow{b} q_4 \wedge q_3 \xrightarrow{a} q_4.$$

(The global transition system of a distributed system satisfies ID and FD.)

The (relaxed) synthesis problem considered in [SEM03] is: Given a distribution Δ and a *deterministic* transition system TS , synthesize an asynchronous automaton \mathcal{AA} over Δ such that $L(\mathcal{AA}) \subseteq L(TS)$ and $\Sigma(\mathcal{AA}) = \Sigma(TS)$ ⁹. This problem was shown to be undecidable in general and the heuristic proposed was to search only for asynchronous automata language equivalent to a *subautomaton* \mathcal{A} of TS satisfying ID and FD. Therefore, the implementation of SYNASYNC [SEM03] includes a heuristic to solve the following NP-complete problem:

Problem 28. (SubautIDFD) Given a transition system TS , find a subautomaton \mathcal{A} with $\Sigma(\mathcal{A}) = \Sigma(TS)$, reachable, deadlock-free, and satisfying ID and FD.

The basic idea is then to ‘unfold’ the subautomaton into an asynchronous automaton accepting the same language (see [SEM03]). Here we propose the following new heuristic, which has also been implemented with SMODELS, that tries to *directly* find an asynchronous automaton in the class of subautomata (with this heuristic, we try to avoid the unfolding procedure which may, theoretically, produce asynchronous automata superexponentially larger than the input):

Problem 29. (SubautAsync) Given a transition system TS , find a subautomaton \mathcal{A} with $\Sigma(\mathcal{A}) = \Sigma(TS)$, reachable, deadlock-free, and isomorphic to an asynchronous automaton.

The main idea behind the implementation is to ‘guess’ the transitions of the subautomaton and then to test the required properties. The logic program code was optimized to include some rudimentary symmetry reductions and the relaxation obtained by dropping the condition AA₂ (see Corollary 13).

⁸The label splitting cannot solve the conflicts without changing the distribution and the silent events must have the whole set *Proc* as domain, and so we force a global synchronization, which is not something that we would like to do in a concurrent setting.

⁹This condition is used to rule out some unwanted (trivial) synthesis solutions.

We have implemented using SMOBELS the above heuristics SubautIDFD and SubautAsync (Problems 28,29) and applied them to parametrized benchmarks of the mutual exclusion and dining philosophers problems. The experimental results can be found in the Appendix B.2 together with a short discussion.

We end the section with some remarks. There are alternative ways to find stable models of a logic program. The CMOBELS2 system is a viable alternative to SMOBELS in this domain as shown by the experiments based on earlier versions of our synthesis implementations [GLM04] (neither of the systems is consistently better than the other). It would also be interesting to see how a recently introduced new translation of the stable model semantics to SAT [Jan03] performs on our examples.

7 Conclusions

A summary of the complexity results obtained is presented in the introduction. We discover that the models of synchronous products of transition systems and asynchronous automata have similar complexities for the implementability test. For both models, deciding the implementability modulo isomorphism provides a distributed implementation *for free*. For implementability modulo language equivalence, this bonus is still available for synchronous products (recall the algorithm of deciding Problem 16). This is not the case for asynchronous automata for which the computationally expensive construction of Zielonka is the best known approach to be used after we have decided that the specification is implementable. However, there is a balance. The complexity results suggest that starting with a deterministic specification is an advantage for asynchronous automata. Also, the asynchronous automata are strictly more expressive than the synchronous products (for the case studies in [SEM03], solutions for the synthesis problem were obtained for asynchronous automata, but not for synchronous products, due to the expressiveness power of the former).

A Appendix

A.1 Proofs of Remarks 6 and 7

Proof of Remark 6.

Let $i \in [1..n]$ and $q \in Q$. Following SP_3 , for each $p \in \text{dom}(a_{x_i}) = \{p_{x_i}, p_{\bar{x}_i}\}$, we try to choose q_p and q'_p such that $q_p \xrightarrow{a_{x_i}} q'_p$ and $q \equiv_p q_p$. Since the only transitions labeled with a_{x_i} are $q_{x_i}^0 \xrightarrow{a_{x_i}} q_{x_i}$ and $q_{x_i}^0 \xrightarrow{a_{x_i}} q'_{x_i}$, q_p must be equal to $q_{x_i}^0$ and q'_p must belong to $\{q_{x_i}, q'_{x_i}\}$, for each $p \in \text{dom}(a_{x_i})$. Moreover, if in $q \equiv_p q_p = q_{x_i}^0$, we instantiate p with p_{x_i} (from $\text{dom}(a_{x_i})$), we obtain $q \equiv_{p_{x_i}} q_{x_i}^0$. Since the $\equiv_{p_{x_i}}$ -equivalence class of $q_{x_i}^0$ is $\{q_{x_i}^0\}$ (see Table 3), we deduce that $q = q_{x_i}^0$. We have now that the hypotheses of SP_3 are satisfied.

For the various choices for $q'_p \in \{q_{x_i}, q'_{x_i}\}$ with $p \in \{p_{x_i}, p_{\bar{x}_i}\}$, we will give a q' such that $q = q_{x_i}^0 \xrightarrow{a_{x_i}} q'$ and $q' \equiv_p q'_p$ for each $p \in \{p_{x_i}, p_{\bar{x}_i}\}$: If $q'_{p_{x_i}} = q'_{p_{\bar{x}_i}} := q_{x_i}$, take $q' := q_{x_i}$. If $q'_{p_{x_i}} = q'_{p_{\bar{x}_i}} := q'_{x_i}$, take $q' := q'_{x_i}$. If $q'_{p_{x_i}} := q_{x_i}$ and $q'_{p_{\bar{x}_i}} := q'_{x_i}$, we have two subcases: If x_i is **False**, take $q' := q'_{x_i}$. This is correct, because we have $q'_{x_i} \equiv_{p_{x_i}} q_{x_i}$ (by Step 2) and $q'_{x_i} \equiv_{p_{\bar{x}_i}} q'_{x_i}$ (by reflexivity). If x_i is **True**, take $q' := q_{x_i}$. This is correct for similar reasons as above. The last case, $q'_{p_{x_i}} := q'_{x_i}$ and $q'_{p_{\bar{x}_i}} := q_{x_i}$, is similar to the above one. \square

Proof of Remark 7.

(\Rightarrow) Assume that SP_3 holds for the given action a . By contradiction, assume that there exists $q \neq q_a$ such that $q \equiv_{\text{dom}(a)} q_a$. The hypothesis of SP_3 holds for the above a , q , and q_p, q'_p chosen to be q_a, q'_a , respectively. Then, there must exist q' such that $q \xrightarrow{a} q'$ (and also $q' \equiv_p q'_a, \forall p \in \text{dom}(a)$). But this is a contradiction, because $q \xrightarrow{a} q'$ would be an a -labeled transition different than the supposedly unique transition $q_a \xrightarrow{a} q'_a$.

(\Leftarrow) Assume now that $\forall q \neq q_a \exists p \in \text{dom}(a) : q \not\equiv_p q_a$. We must prove that SP_3 holds for the given a . Let $q, q_p, q'_p \in Q$ such that $q_p \xrightarrow{a} q'_p$ and $q \equiv_p q_p$, for each $p \in \text{dom}(a)$. Since $q_a \xrightarrow{a} q'_a$ is the only a -labeled transition, we have that $q_p = q_a$ and $q'_p = q'_a, \forall p \in \text{dom}(a)$. This implies $q \equiv_{\text{dom}(a)} q_a$ (because $q \equiv_p q_p, \forall p \in \text{dom}(a)$). Using the (\Leftarrow)-assumption above, we necessarily have that $q = q_a$. Now, it is easy to find a state q' satisfying $q \xrightarrow{a} q'$ and $q' \equiv_p q'_p = q'_a, \forall p \in \text{dom}(a)$: We simply choose $q' := q'_a$. \square

A.2 Proof of Corollary 9

The problem is in NP for the same reasons given in the proof of Theorem 5. To prove that the problem is NP-hard, we use a reduction from the implementability problem for synchronous products modulo isomorphism. Given a distribution $(\Sigma, Proc, \Delta)$ and a (possibly nondeterministic) transition system TS , we construct a new distribution $(\Sigma', Proc, \Delta')$ (over the same set of processes $Proc$) and a new transition system TS' such that: There exist $(\equiv_p)_{p \in Proc}$ on the states of TS satisfying SP_1 - SP_2 - SP_3 in Theorem 4 (i.e., TS is isomorphic

to a synchronous product of transition systems over $(\Sigma, Proc, \Delta)$ if and only if there exist $(\equiv'_p)_{p \in Proc}$ on the states of TS' satisfying SP_1 and SP_3 for the new $(\Sigma', Proc, \Delta')$.

For each $(\Sigma, Proc, \Delta)$ and $TS = (Q, \Sigma, \rightarrow, I)$, we build $(\Sigma', Proc, \Delta')$ and $TS' = (Q', \Sigma', \rightarrow', I')$ in the following way:

- We add one new action for each state of TS : $\Sigma' := \Sigma \cup \{a_q \mid q \in Q\}$ with the new distribution relation: $\Delta' := \Delta \cup \{(a_q, p) \mid q \in Q, p \in Proc\}$.
The domains generated by Δ' are $dom'(a) := dom(a)$ for all $a \in \Sigma$ and $dom'(a_q) := Proc$ for all $q \in Q$.
- $Q' := Q \cup \{q_0\}$ where q_0 is a new state and $I' := I$.
- $\rightarrow' := \rightarrow \cup \{(q, a_q, q_0) \mid q \in Q\}$. For simplicity, we denote \rightarrow' also by \rightarrow .

For the direct implication, let us assume that there exist $(\equiv_p)_{p \in Proc}$ on the states of TS satisfying SP_1 - SP_2 - SP_3 . We extend each $\equiv_p \subseteq Q \times Q$ to $\equiv'_p \subseteq Q' \times Q'$, simply by choosing $\equiv'_p := \equiv_p \cup \{(q_0, q_0)\}$ (i.e., the new state q_0 is equivalent only to itself). We prove that SP_1 and SP_3 hold for $(\equiv'_p)_{p \in Proc}$:

SP_1 : Because SP_1 holds for the transitions in TS and $dom'(a) := dom(a)$ for all $a \in \Sigma$, we only have to prove that SP_1 holds for the newly added transitions $q \xrightarrow{a_q} q_0$, but this is trivial given the fact that $dom'(a_q) := Proc$.

SP_3 : We prove that SP_3 holds for each $a \in \Sigma'$ distinguishing two cases:

- For $a \in \Sigma$, SP_3 holds in TS' because SP_3 holds for TS (this is easy).
- For $a \in \Sigma' \setminus \Sigma$, by construction, $dom(a) = Proc$ and there exists $q \in Q$ such that $a = a_q$ and the transition $q \xrightarrow{a} q_0$. Since the transition $q \xrightarrow{a} q_0$ is *the only* one labeled with $a = a_q$ in TS' , we prove that SP_3 holds for a in TS' , applying Remark 7: We have to prove that for each $r \in Q'$ with $r \neq q$, there exists a process $p \in dom(a) = Proc$ such that $r \not\equiv'_p q$. We have two subcases:
 - For $r \in Q$, we have that r and q belong to Q and $r \neq q$. From the hypothesis, $(\equiv_p)_{p \in Proc}$ satisfies SP_2 . In this case, we can apply Remark 8 for $r \neq q$ and we obtain that there exists a process $p \in Proc$ such that $r \not\equiv_p q$, so also $r \not\equiv'_p q$.
 - For $r = q_0$, by construction, $r = q_0 \not\equiv'_p q$ for any $q \in Q$ and $p \in Proc$.

For the reverse implication, assume that there exist $(\equiv'_p)_{p \in Proc}$ on the states of TS' satisfying SP_1 and SP_3 . Let us choose $(\equiv_p)_{p \in Proc}$ as the projection of $(\equiv'_p)_{p \in Proc}$ on $Q \times Q$. It is easy to see that SP_1 and SP_3 are satisfied for TS and $(\equiv_p)_{p \in Proc}$ because the same properties hold for TS' and $(\equiv'_p)_{p \in Proc}$. To prove SP_2 , we use the equivalent condition given by Remark 8: SP_2 holds for TS and $(\equiv_p)_{p \in Proc}$ iff for each pair of states $q \neq r$ from Q , there exists $p \in Proc$ such that $q \not\equiv_p r$. Let $q \neq r$ from Q . Since $q \xrightarrow{a_q} q_0$ is the only transition labeled with a_q from TS' and SP_3 holds for TS' and $(\equiv'_p)_{p \in Proc}$, we can apply Remark 7 and we obtain that there exists a process $p \in dom'(a_q) = Proc$ such that $q \not\equiv'_p r$. This implies also that $q \not\equiv_p r$ (because $q, r \in Q$). \square

A.3 Proof of Theorem 12

First, it is easy to see that the problem is in NP: Given a distribution $(\Sigma, Proc, \Delta)$ and a transition system TS , a nondeterministic machine can ‘guess’ a family of equivalences $(\equiv_k)_{k \in Proc}$ and then verify in *polynomial* time (in the size of the distribution and of the transition system) whether the properties AA₁–AA₃ from Theorem 11 are satisfied or not.

For the NP-hardness part, we use a polynomial reduction from the classical SAT problem. Let ϕ be a formula in conjunctive normal form with variables x_1, \dots, x_n appearing in the clauses c_1, \dots, c_m . For technical reasons, we construct first a new formula ϕ' that satisfy the following properties:

1. each variable appears in at least two different clauses,
2. each clause contains at least two different literals, and
3. ϕ' is satisfiable if and only if ϕ is satisfiable.

The formula ϕ' is constructed from ϕ as follows. We start with ϕ' being equal to a new clause $c_0 := x_0 \vee \overline{x_0} \vee x_1 \vee x_2 \vee \dots \vee x_n$, where x_0 is a fresh variable. Then we add to ϕ' the clauses of ϕ that contain at least two different literals. Finally, if $c_j := x_i$ (resp. $c_j := \overline{x_i}$) is a clause of ϕ , we add to ϕ' two new clauses $x_i \vee x_0$ and $x_i \vee \overline{x_0}$ (resp. $\overline{x_i} \vee x_0$ and $\overline{x_i} \vee \overline{x_0}$). It is easy to see that ϕ' satisfies the three properties above. For convenience, we denote ϕ' also by ϕ in the following.

We will construct a distribution $(\Sigma_\phi, Proc_\phi, \Delta_\phi)$ and a (nondeterministic) transition system $TS_\phi = (Q_\phi, \Sigma_\phi, \rightarrow_\phi, I_\phi)$ such that: ϕ is satisfiable if and only if TS_ϕ is isomorphic to an asynchronous automaton over Δ_ϕ . To relieve a bit the notation, we will drop all ϕ indices.

First, the set of processes $Proc$ consists of one process for each (positive or negative) literal from each clause:

$$Proc := \{p_{x_i c_j} \mid j \in [0..m], x_i \in c_j\} \cup \{p_{\overline{x_i} c_j} \mid j \in [0..m], \overline{x_i} \in c_j\}.$$

Then, the set Σ of actions and their domains (which determine Δ) consist of:

- one action for each positive literal from each clause: $\{a_{x_i c_j} \mid j \in [0..m], x_i \in c_j\}$ with $dom(a_{x_i c_j}) := Proc \setminus \{p_{x_i c_j}\}$.
- one action for each negative literal from each clause: $\{a_{\overline{x_i} c_j} \mid j \in [0..m], \overline{x_i} \in c_j\}$ with $dom(a_{\overline{x_i} c_j}) := Proc \setminus \{p_{\overline{x_i} c_j}\}$.
- one action for each variable: $\{a_{x_i} \mid i \in [0..n]\}$ with the domain of a_{x_i} consisting of the processes associated to the literals where x_i appears:
$$dom(a_{x_i}) := \bigcup_{j: x_i \in c_j} \{p_{x_i c_j}\} \cup \bigcup_{j: \overline{x_i} \in c_j} \{p_{\overline{x_i} c_j}\}.$$
- one action for each clause: $\{a_{c_j} \mid j \in [0..m]\}$ with the domain of a_{c_j} consisting of the processes associated to the literals of c_j :
$$dom(a_{c_j}) := \bigcup_{i: x_i \in c_j} \{p_{x_i c_j}\} \cup \bigcup_{i: \overline{x_i} \in c_j} \{p_{\overline{x_i} c_j}\}.$$

Last, we construct the transition system TS : The state space Q consist of:

- six states for each variable: $\{q_{x_i}^0, q_{x_i}^1, q'_{x_i}, q_{x_i}, q_{x_i}^F, q_{x_i}^T \mid i \in [0..n]\}$ and
- three states for each clause: $\{q_{c_j}, q'_{c_j}, q_{c_j}^0 \mid j \in [0..m]\}$.

Fig. 5. The transition system TS associated to $\phi = (x_1 \vee x_2) \wedge (\overline{x_2} \vee \overline{x_3})$ (without the states and transitions associated to clause c_0)

The transition relation $\rightarrow \subseteq Q \times \Sigma \times Q$ is defined below:

- for each $i \in [0..n]$: $q_{x_i}^0 \xrightarrow{a_{x_i}} q'_{x_i}$, $q_{x_i}^0 \xrightarrow{a_{x_i}} q_{x_i}$, and $q_{x_i}^0 \xrightarrow{a} q_{x_i}^1$ for each action $a \in \{a_{x_i c_j} \mid x_i \in c_j\} \cup \{a_{\overline{x_i} c_j} \mid \overline{x_i} \in c_j\}$.
- for each $i \in [0..n]$: $q_{x_i}^1 \xrightarrow{a_{x_i}} q_{x_i}^F$, $q_{x_i}^1 \xrightarrow{a_{x_i}} q_{x_i}^T$.
- for each $j \in [0..m]$: $q_{c_j} \xrightarrow{a_{x_i c_j}} q_{x_i}$ for $x_i \in c_j$, $q_{c_j} \xrightarrow{a_{\overline{x_i} c_j}} q_{x_i}$ for $\overline{x_i} \in c_j$, and $q_{c_j} \xrightarrow{a_{c_j}} q_{c_j}^0$.
- for each $j \in [0..m]$: $q'_{c_j} \xrightarrow{a_{x_i c_j}} q_{x_i}^F$ for $x_i \in c_j$ and $q'_{c_j} \xrightarrow{a_{\overline{x_i} c_j}} q_{x_i}^T$ for $\overline{x_i} \in c_j$.

The set of initial states I is chosen such that all states of Q are reachable from I . For instance, $I := \{q_{x_i}^0, q_{x_i}^1 \mid i \in [0..n]\} \cup \{q_{c_j}, q'_{c_j} \mid j \in [0..m]\}$. (It is easy to modify the construction such that there is only one initial state.)

An example is provided in Fig. 5. We omitted, for legibility, the states q_{c_0} , q'_{c_0} , and $q_{c_0}^0$ and their associated transitions (those states were introduced for some consistency reasons - see construction of ϕ'). Also, we did not mark the initial states, because they do not play any rôle here.

The ‘choice gadget’ is provided by the six states for each variable x_i and their associated transitions. The ‘value’ of each choice is then propagated further to the clauses using the transitions labeled $a_{x_i c_j}$ and $a_{\overline{x_i} c_j}$, respectively. More precisely, to each clause we forward only the information that a variable was set to **False** in such a way that: A clause c_j has all the literals evaluated to **False** iff the condition AA₃ is violated for $q_1 := q_{c_j}$, $q'_1 := q'_{c_j}$, $q_2 := q_{c_j}$.

The above construction is polynomial in the size of the initial formula ϕ and we claim that ϕ is satisfiable if and only if TS is isomorphic to an asynchronous automaton over Δ (given by dom).

First Implication. We first prove the easier part: ϕ is not satisfiable implies TS is not isomorphic to an asynchronous automaton over Δ . If ϕ is not satisfiable, then for any assignment of the variables x_0, \dots, x_n there exists a clause that evaluates to **False**. We must show that in this case, there are no $(\equiv_p)_{p \in Proc}$ satisfying all AA₁–AA₃.

By contradiction, assume that there exist $(\equiv_p)_{p \in Proc}$ satisfying all AA₁–AA₃.

For each $i \in [0..n]$, from $q_{x_i}^0 \xrightarrow{a} q_{x_i}^1$ for all $a \in \{a_{x_i c_j} \mid x_i \in c_j\} \cup \{a_{\overline{x_i} c_j} \mid \overline{x_i} \in c_j\}$, using AA₁, we have that $q_{x_i}^0 \equiv_p q_{x_i}^1$ for all $p \in \{p_{x_i c_j} \mid x_i \in c_j\} \cup \{p_{\overline{x_i} c_j} \mid \overline{x_i} \in c_j\}$, and so $q_{x_i}^0 \equiv_{\text{dom}(a_{x_i})} q_{x_i}^1$. Next, from $q_{x_i}^0 \equiv_{\text{dom}(a_{x_i})} q_{x_i}^1$ and $q_{x_i}^0 \xrightarrow{a_{x_i}} q_{x_i}$, using AA₃, we have that either $q_{x_i} \equiv_{\text{dom}(a_{x_i})} q_{x_i}^F$, or $q_{x_i} \equiv_{\text{dom}(a_{x_i})} q_{x_i}^T$, but *not both in the same time* (otherwise, by transitivity we have $q_{x_i}^F \equiv_{\text{dom}(a_{x_i})} q_{x_i}^T$ and also $q_{x_i}^F \equiv_{\text{Proc} \setminus \text{dom}(a_{x_i})} q_{x_i}^T$ by AA₁ applied to $q_{x_i}^F \xleftarrow{a_{x_i}} q_{x_i}^1 \xrightarrow{a_{x_i}} q_{x_i}^T$, so $q_{x_i}^F \equiv_{\text{Proc}} q_{x_i}^T$ and this would contradict AA₂). Let us choose an assignment of the variables given by the equivalences in the following way. For each $i \in [0..n]$:

$$x_i \text{ is evaluated to } \mathbf{False} \text{ if and only if } q_{x_i} \equiv_{\text{dom}(a_{x_i})} q_{x_i}^F.$$

Because ϕ is not satisfiable, there exists a clause, say c_k , that has all its literals evaluated to **False**. Let x_i be a positive literal in c_k (if any). Since the literal x_i is evaluated to **False**, we have that the variable x_i is **False**, so $q_{x_i} \equiv_{\text{dom}(a_{x_i})} q_{x_i}^F$ and this implies $q_{x_i} \equiv_{p_{x_i c_k}} q_{x_i}^F$ (because $p_{x_i c_k} \in \text{dom}(a_{x_i})$). In addition, we have $q_{c_k} \xrightarrow{a_{x_i c_k}} q_{x_i}$ and $q'_{c_k} \xrightarrow{a_{x_i c_k}} q_{x_i}^F$ (see the construction of TS) and, using AA₁, we deduce that $q_{c_k} \equiv_{p_{x_i c_k}} q_{x_i}$ and $q'_{c_k} \equiv_{p_{x_i c_k}} q_{x_i}^F$. By transitivity of $\equiv_{p_{x_i c_k}}$, we obtain that $q_{c_k} \equiv_{p_{x_i c_k}} q_{c_k}$. A similar argument for the negative literals $\overline{x_i}$ in c_k (if any), proves that $q_{c_k} \equiv_{p_{\overline{x_i} c_k}} q'_{c_k}$.

Summing up, q_{c_k} and q'_{c_k} are equivalent on all the processes associated to the literals in c_k , and so, by the definition of $\text{dom}(a_{c_k})$, we obtain that $q_{c_k} \equiv_{\text{dom}(a_{c_k})} q'_{c_k}$. But this contradicts AA₃ because $q_{c_k} \xrightarrow{a_{c_k}} q_{c_k}^0$ and there is no state q' such that $q'_{c_k} \xrightarrow{a_{c_k}} q'$.

Second Implication. We move now to the second part of the proof, assuming that ϕ is satisfiable. Then, there exists an assignment to the variables x_0, \dots, x_n such that each clause is **True**. We prove that TS is isomorphic to an asynchronous automaton over Δ . For that, we construct a family of equivalences $(\equiv_p)_{p \in \text{Proc}}$ in the following way:

- Step 0** For each $p \in \text{Proc}$, initialize the binary relation $\equiv_p \subseteq Q \times Q$ to \emptyset .
- Step 1** For each $q \xrightarrow{a} q'$, choose $q \equiv_p q'$ for each $p \in \text{Proc} \setminus \text{dom}(a)$.
- Step 2** For each $i \in [0..n]$, if variable x_i is evaluated to **False**, then choose $q_{x_i} \equiv_{\text{dom}(a_{x_i})} q_{x_i}^F$ and $q'_{x_i} \equiv_{\text{dom}(a_{x_i})} q_{x_i}^T$, otherwise choose $q_{x_i} \equiv_{\text{dom}(a_{x_i})} q_{x_i}^T$ and $q'_{x_i} \equiv_{\text{dom}(a_{x_i})} q_{x_i}^F$.
- Step 3** For each $p \in \text{Proc}$, close \equiv_p under reflexivity, symmetry, and transitivity.

We prove that the chosen $(\equiv_p)_{p \in \text{Proc}}$ satisfy all AA₁–AA₃ and this implies, by Theorem 11, that TS is isomorphic to an asynchronous automaton over Δ .

Let us start making some remarks:

- Step 1 directly imposes AA₁ to be satisfied.
- Step 2 implements the choice gadget for the variables: For each $i \in [0..n]$, from $q_{x_i}^0 \xrightarrow{a} q_{x_i}^1$ for all $a \in \{a_{x_i c_j} \mid x_i \in c_j\} \cup \{a_{\overline{x_i} c_j} \mid \overline{x_i} \in c_j\}$, using Step 1 (i.e., AA₁), we have that $q_{x_i}^0 \equiv_{\text{dom}(a_{x_i})} q_{x_i}^1$. It is not difficult to check that

Table 6. The equivalence classes constructed in the 2nd part of the proof of Th. 12

	$x_i = \text{False}$	$x_i = \text{True}$
$\equiv_{p_{x_i c_j}}$ (for $x_i \in c_j$)	$\{q_{x_i}^0, q_{x_i}^1\}, \{q'_{x_i}, q_{x_i}^T\},$ $\{q_{x_i}, q_{x_i}^F, q_{c_j}, q'_{c_j}\}, \{q_{c_j}^0\},$ for each $i' \neq i, \{q_{x_{i'}}^0, q'_{x_{i'}}, q_{x_{i'}}\},$ $\{q_{x_{i'}}^1, q_{x_{i'}}^F, q_{x_{i'}}^T\},$ and for each $j' \neq j, \{q_{c_{j'}}^0, q'_{c_{j'}}\}, \{q'_{c_{j'}}\}$	$\{q_{x_i}^0, q_{x_i}^1\}, \{q'_{x_i}, q_{x_i}^F, q'_{c_j}\},$ $\{q_{x_i}, q_{x_i}^T, q_{c_j}\}, \{q_{c_j}^0\}$ for each $i' \neq i, \{q_{x_{i'}}^0, q'_{x_{i'}}, q_{x_{i'}}\},$ $\{q_{x_{i'}}^1, q_{x_{i'}}^F, q_{x_{i'}}^T\},$ and for each $j' \neq j, \{q_{c_{j'}}^0, q'_{c_{j'}}\}, \{q'_{c_{j'}}\}$
$\equiv_{p_{\bar{x}_i c_j}}$ (for $\bar{x}_i \in c_j$)	$\{q_{x_i}^0, q_{x_i}^1\}, \{q'_{x_i}, q_{x_i}^T, q'_{c_j}\},$ $\{q_{x_i}, q_{x_i}^F, q_{c_j}\}, \{q_{c_j}^0\}$ for each $i' \neq i, \{q_{x_{i'}}^0, q'_{x_{i'}}, q_{x_{i'}}\},$ $\{q_{x_{i'}}^1, q_{x_{i'}}^F, q_{x_{i'}}^T\},$ and for each $j' \neq j, \{q_{c_{j'}}^0, q'_{c_{j'}}\}, \{q'_{c_{j'}}\}$	$\{q_{x_i}^0, q_{x_i}^1\}, \{q'_{x_i}, q_{x_i}^F\},$ $\{q_{x_i}, q_{x_i}^T, q_{c_j}, q'_{c_j}\}, \{q_{c_j}^0\},$ for each $i' \neq i, \{q_{x_{i'}}^0, q'_{x_{i'}}, q_{x_{i'}}\},$ $\{q_{x_{i'}}^1, q_{x_{i'}}^F, q_{x_{i'}}^T\},$ and for each $j' \neq j, \{q_{c_{j'}}^0, q'_{c_{j'}}\}, \{q'_{c_{j'}}\}$

AA₃ holds for the states $q_{x_i}^0, q_{x_i}^1$ and each of the a_{x_i} -labeled edges coming out of them. For example, let us take $q_{x_i}^0, q_{x_i}^1$, for which we have $q_{x_i}^0 \xrightarrow{a_{x_i}} q_{x_i}$ and $q_{x_i}^0 \equiv_{\text{dom}(a_{x_i})} q_{x_i}^1$. The first part of AA₃ is satisfied, so there must exist a state q' such that $q_{x_i}^1 \xrightarrow{a_{x_i}} q'$ and $q_{x_i} \equiv_{\text{dom}(a_{x_i})} q'$. If x_i is **False**, we take $q' := q_{x_i}^F$, otherwise $q' := q_{x_i}^T$. Loosely speaking, we can tell the value of x_i checking which of the states $q_{x_i}^F$ and $q_{x_i}^T$ is equivalent on $\text{dom}(a_{x_i})$ with q_{x_i} .

- Step 3 ensures that $(\equiv_p)_{p \in \text{Proc}}$ are equivalences.
- Moreover, Step 3 transmits further the information from the variables to the literals in the clauses. In the example in Fig. 5, x_2 appears in c_1 . If x_2 is evaluated to **False**, then we know that $q_{x_2} \equiv_{\text{dom}(a_{x_2})} q_{x_2}^F$ and this implies $q_{x_2} \equiv_{p_{x_2 c_1}} q_{x_2}^F$. We also have $q_{c_1} \xrightarrow{a_{x_2 c_1}} q_{x_2}$ and $q'_{c_1} \xrightarrow{a_{x_2 c_1}} q_{x_2}^F$ and, using Step 1 (i.e., AA₁), we deduce that $q_{c_1} \equiv_{p_{x_2 c_1}} q_{x_2}$ and $q'_{c_1} \equiv_{p_{x_2 c_1}} q_{x_2}^F$. By Step 3 (i.e., transitivity of $\equiv_{p_{x_2 c_1}}$), we obtain that $q_{c_1} \equiv_{p_{x_2 c_1}} q'_{c_1}$. Therefore, we have indeed that $x_2 = \text{False}$ implies $q_{c_1} \equiv_{p_{x_2 c_1}} q'_{c_1}$ (at the level of equivalences).

Table 6 describes the equivalence classes of our equivalences generated above. Each cell gives the partition of the state space Q into the equivalence classes for each type of process (rows) depending on the value of the associated variable (columns). Each equivalence class is given as a set in curly brackets. It is tedious, but not hard to check the correctness of Table 6. Based on it, we prove that the chosen $(\equiv_p)_{p \in \text{Proc}}$ satisfy AA₃, AA₂, and AA₁ (in this order):

Remark 30. A sufficient condition for AA₃ to hold for $q_1 \neq q_2$ and $q_1 \xrightarrow{a} q'_1$ is that there exists $p \in \text{dom}(a)$ such that $q_1 \not\equiv_p q_2$.

First, Table 7 solves the cases for AA₃. The first column picks a value for q_1 , the second one gives the transition $q_1 \xrightarrow{a} q'_1$ we are considering, while the third column gives a range to q_2 . In the last column we either give a state q'_2 as in the formulation of AA₃ or we give a process $p \in \text{dom}(a)$ such that $q_1 \not\equiv_p q_2$ as in Remark 30. The correctness of the solutions provided is verified using Table 6.

Remark 31. AA₂ holds iff for each $q_1 \neq q_2$, there exists $p \in \text{Proc}$ with $q_1 \not\equiv_p q_2$.

Table 7. Details for the satisfaction of the AA₃ property

q_1	$q_1 \xrightarrow{a} q'_1$	q_2	Why AA ₃ holds (either a state q'_2 or a process $p \in \text{dom}(a)$ are given)
$q_{x_i}^0$	$q_{x_i}^0 \xrightarrow{a_{x_i}} q'_{x_i}$	$\{q_{x_i}^1\}$	We have $q_{x_i}^0 \equiv_{\text{dom}(a_{x_i})} q_{x_i}^1$ (because of Step 1; see also Table 6). If x_i is True , choose $q'_2 := q_{x_i}^F$, otherwise choose $q'_2 := q_{x_i}^T$.
		$Q \setminus \{q_{x_i}^0, q_{x_i}^1\}$	$p := p_{x_i c_0}$.
	$q_{x_i}^0 \xrightarrow{a_{x_i}} q_{x_i}$	Similar to the case $q_{x_i}^0 \xrightarrow{a_{x_i}} q'_{x_i}$ above.	
	$q_{x_i}^0 \xrightarrow{a_{x_i c_j}} q_{x_i}^1$ (for $x_i \in c_j$)	$\{q_{x_i}^1\}$	$p := p_{x_i' c_0}$, where $i' \neq i$ (by constr. $x_{i'} \in c_0$).
		$Q \setminus \{q_{x_i}^0, q_{x_i}^1\}$	p can be any process from $\text{dom}(a_{x_i}) \setminus \{p_{x_i c_j}\}$. Such p exists, because $\text{card}(\text{dom}(a_{x_i})) \geq 2$ (remember that we forced each variable of ϕ to appear in at least two clauses).
$q_{x_i}^0 \xrightarrow{a_{\bar{x}_i c_j}} q_{x_i}^1$ (for $\bar{x}_i \in c_j$)	Similar to the case $q_{x_i}^0 \xrightarrow{a_{x_i c_j}} q_{x_i}^1$ above.		
$q_{x_i}^1$	Similar to the case $q_{x_i}^0$ above.		
q_{c_j}	$q_{c_j} \xrightarrow{a_{x_i c_j}} q_{x_i}$ (for $x_i \in c_j$)	$\{q_{c_j}^0\}$	We choose p to be the process associated to a literal ℓ of c_j different ^a from x_i . So, $p := p_{\ell c_j}$ for $\ell \in c_j$ and $\ell \neq x_i$.
		$Q \setminus \{q_{c_j}, q_{c_j}^0\}$	$p := p_{\ell c_{j'}}$, for $c_{j'}$ different ^b from c_j and $\ell \in c_{j'}$.
	$q_{c_j} \xrightarrow{a_{\bar{x}_i c_j}} q_{x_i}$ (for $\bar{x}_i \in c_j$)	Similar to the case $q_{c_j} \xrightarrow{a_{x_i c_j}} q_{x_i}$ above.	
	$q_{c_j} \xrightarrow{a_{c_j}} q_{c_j}^0$	Since c_j evaluates to True , there exists a literal ℓ of c_j evaluated to True . Assume $\ell = x_i$, such that $x_i \in c_j$ and $x_i = \text{True}$ (a similar analysis is made if ℓ is negative). Then:	
		$\{q_{x_i}, q_{x_i}^T\}$	$p := p_{\ell c_j}$ for $\ell \in c_j$ and $\ell \neq x_i$ ^a .
	$Q \setminus \{q_{c_j}, q_{x_i}, q_{x_i}^T\}$	$p := p_{x_i c_j}$.	
$q_{c_j}^0$	Similar to the case q_{c_j} above.		

^aSuch different literal ℓ exists because we forced each clause to contain at least two different literals.

^bOur formula ϕ contains at least two clauses.

Table 8. Details for the AA₂ property (only cases not solved already in Table 7)

q_1	q_2	Why AA ₂ holds (a process $p \in \text{Proc}$ is given)
q'_{x_i}	$\{q_{x_i}\}$	$p := p_{x_i c_0}$ (by construction $x_i \in c_0$).
	$Q' \setminus \{q'_{x_i}, q_{x_i}\}$	$p := p_{x_i' c_0}$, where $i' \neq i$ (by construction $x_{i'} \in c_0$).
q_{x_i}	$Q' \setminus \{q_{x_i}, q'_{x_i}\}$	$p := p_{x_i' c_0}$, where $i' \neq i$ (by construction $x_{i'} \in c_0$).
$q_{x_i}^F$	$\{q_{x_i}^T\}$	$p := p_{x_i c_0}$ (by construction $x_i \in c_0$).
	$Q' \setminus \{q_{x_i}^F, q_{x_i}^T\}$	$p := p_{x_i' c_0}$, where $i' \neq i$ (by construction $x_{i'} \in c_0$).
$q_{x_i}^T$	$Q' \setminus \{q_{x_i}^T, q_{x_i}^F\}$	$p := p_{x_i' c_0}$, where $i' \neq i$ (by construction $x_{i'} \in c_0$).
$q_{c_j}^0$	$Q' \setminus \{q_{c_j}^0\}$	$p := p_{\ell c_j}$, where ℓ is a literal of c_j .

Table 8 presents only the cases for which Table 7 did not give a process to ‘distinguish’ two different states q_1 (column 1) and q_2 (in the range given in column 2), i.e., we give $p \in Proc$ such that $q_1 \not\equiv_p q_2$. More precisely, we only have to consider pairs of states from the subset:

$$Q' := \{q'_{x_i}, q_{x_i}, q_{x_i}^F, q_{x_i}^T \mid i \in [0..n]\} \cup \{q_{c_j}^0 \mid j \in [0..m]\}.$$

(Note that the elements of Q' are those state with no outgoing edges.)

Condition AA₁ is fulfilled by construction (Step 1). □

A.4 Details for the proofs in Section 4.2

Proof of Proposition 22

The direct implication is easy. For the reverse, let T be a prefix-closed regular trace language. From [Zie89, Th. 4.8], there exists a safe asynchronous automaton \mathcal{AA} with a set of global initial states I and a set of global accepting states F such that $L(\mathcal{AA}, F) = T$, where $L(\mathcal{AA}, F) := \{w \in \Sigma^* \mid \exists q^{in} \in I, q \in F, q^{in} \xrightarrow{w} q\}$.

We show that $L(\mathcal{AA}, F) = L(\mathcal{AA})$, where $L(\mathcal{AA})$ is our definition of language containing all the runs starting in an initial state of I .

Since inclusion $L(\mathcal{AA}, F) \subseteq L(\mathcal{AA})$ is obvious, we only prove $L(\mathcal{AA}) \subseteq L(\mathcal{AA}, F)$ using the hypothesis that $T = L(\mathcal{AA}, F)$ is prefix-closed. Let $w \in L(\mathcal{AA})$. Then, there exists the run $q^{in} \xrightarrow{w} q$ with $q^{in} \in I$ in \mathcal{AA} . By construction, \mathcal{AA} is a *safe* asynchronous automaton, so any run of \mathcal{AA} from an initial state can be extended to an accepting run. In particular, w can be extended to a run $q^{in} \xrightarrow{w'} q'$ with $q' \in F$. Hence w is a prefix of $w' \in L(\mathcal{AA}, F)$ and since $L(\mathcal{AA}, F)$ is prefix-closed, we conclude that $w \in L(\mathcal{AA}, F)$. □

Proof of Theorem 23

The ‘totality problem for regular languages’ is defined as: Given a nondeterministic finite automata \mathcal{A} over the alphabet Σ , is the language accepted by \mathcal{A} (given by a set of accepting states) equal to Σ^* ? It is a classical result that this problem is PSPACE-complete [GJ79].

We reduce the above totality problem to the implementability problem for asynchronous automata modulo language equivalence. For each nondeterministic finite automaton $\mathcal{A} = (Q, \Sigma, \rightarrow, \{q^{in}\}, \{q^{acc}\})$ where Q is the set of states, Σ the alphabet, $\rightarrow \subseteq Q \times \Sigma \times Q$ the transition relation, q^{in} the initial state, and q^{acc} the accepting state (we can suppose w.l.o.g. that \mathcal{A} has only one initial, respectively only one accepting state), we build a distribution $(\Sigma', Proc, \Delta)$ and a transition system TS over Σ' such that $L(\mathcal{A}, \{q^{acc}\}) = \Sigma^*$ iff $L(TS)$ is a trace language (this is enough according to Proposition 22).

We choose $\Sigma' := \Sigma \cup \{a, b, c\}$ with $a, b, c \notin \Sigma$, $Proc := \{1, 2\}$, and Δ such that $\Sigma_{loc}(1) := \Sigma \cup \{a, b\}$ and $\Sigma_{loc}(2) := \Sigma \cup \{a, c\}$. We can see that $b \parallel c$ is the only independence generated by Δ . Then, we choose the transition system $TS := (Q', \Sigma', \rightarrow', \{q_0\})$ as in Fig. 3 (left). More precisely, we have

$$- Q' := Q \cup \{q_0, q_1, q_2, q_3, q'_2, q'_3\} \text{ and}$$

$$\begin{aligned}
- \rightarrow' := & \{q_0 \xrightarrow{a} q_1\} \cup \{q_1 \xrightarrow{\alpha} q_1 \mid \alpha \in \Sigma\} \cup \{q_1 \xrightarrow{b} q_2 \xrightarrow{c} q_3\} \\
& \cup \{q_0 \xrightarrow{a} q^{in}\} \cup (\rightarrow) \cup \{q^{acc} \xrightarrow{c} q'_2 \xrightarrow{b} q'_3\}.
\end{aligned}$$

For a language L , we denote by $Prefix(L)$ the language which contains all the prefixes of the words of L . Then, it is easy to see that

$$L(TS) = Prefix(a\Sigma^*bc + aL(\mathcal{A}, \{q^{acc}\})cb).$$

If we assume that $L(\mathcal{A}, \{q^{acc}\}) = \Sigma^*$, then $L(TS) = Prefix(a\Sigma^*(bc + cb))$, which is obviously a trace language (the only independence is $b\|c$). On the other hand, if $L(\mathcal{A}, \{q^{acc}\}) \neq \Sigma^*$, there exists $w \in \Sigma^* \setminus L(\mathcal{A}, \{q^{acc}\})$, which implies that $L(TS)$ is not a trace language because $awbc \in L(TS)$ and $b\|c$, but $awcb \notin L(TS)$.

We mention that our proof is reminiscent of the PSPACE-hardness proof for checking the trace closure of the language of a nondeterministic I-diamond Büchi automaton [Mus94, Th. 7.2.3]. An alternative proof to our result can be obtained modifying the PSPACE-hardness proof of checking the trace closure of the language of a nondeterministic automaton [PWW98, Th. 11]. The difference is that the language of a transition system is always prefix-closed, so the constructions must accommodate this detail (and this is not immediate). \square

Proof of Proposition 24

First, given an *acyclic* transition system TS together with a distribution Δ , checking that $L(TS)$ is *not* trace-closed is in NP. A machine can guess a pair of independent actions $a\|b$ and two strings w, w' and check in polynomial time whether $waw' \in L(TS)$ and $wbaw' \notin L(TS)$ (notice that, since TS is acyclic, the length of w and w' is bounded by the size of TS).

For the coNP-hardness part, we use a reduction from the NP-complete problem of ‘language inequivalence for acyclic finite nondeterministic automata’ (see [GJ79]): Given two *acyclic* nondeterministic finite automata \mathcal{A}_1 and \mathcal{A}_2 over the same alphabet Σ , do they accept different languages?

Given $\mathcal{A}_1 = (Q_1, \Sigma, \rightarrow_1, \{q_1^{in}\}, \{q_1^{acc}\})$ and $\mathcal{A}_2 = (Q_2, \Sigma, \rightarrow_2, \{q_2^{in}\}, \{q_2^{acc}\})$ two acyclic nondeterministic finite automata assumed w.l.o.g. to have only one initial, respectively one accepting state, we construct a transition system TS as in Fig. 3 (right) and a distribution such that $b\|c$ (cf. the proof of Th. 23). We have then:

$$L(TS) = Prefix(aL(\mathcal{A}_1, \{q_1^{acc}\})bc + aL(\mathcal{A}_2, \{q_2^{acc}\})cb),$$

which easily implies that $L(TS)$ is not a trace language if and only if the languages $L(\mathcal{A}_1, \{q_1^{acc}\})$ and $L(\mathcal{A}_2, \{q_2^{acc}\})$ are different. \square

Proof of Theorem 25

To prove the PSPACE-hardness of the implementability problem for synchronous products of transition systems modulo language equivalence, we use the construction of TS and the distribution $(\Sigma', Proc, \Delta)$ from the proof of Th. 23 (see

Fig. 3). We show that $L(\mathcal{A}, \{q^{acc}\}) = \Sigma^*$ iff $L(TS)$ is the language of a synchronous product over Δ : If $L(\mathcal{A}, \{q^{acc}\}) = \Sigma^*$, then $L(TS) = \text{Prefix}(a\Sigma^*(bc + cb))$ and we can easily construct a synchronous product accepting $L(TS)$ (we choose the two local components accepting the projections $\text{Prefix}(a\Sigma^*b)$, respectively $\text{Prefix}(a\Sigma^*c)$). If $L(\mathcal{A}, \{q^{acc}\}) \neq \Sigma^*$, then $L(TS)$ is not a trace language and therefore cannot be the language of a synchronous product (because the language of a synchronous product of transition systems is always a trace language).

For acyclic specifications, it was proved in [Dub86] that the class of *finite* languages accepted by synchronous products is equal to the class of *finite* languages accepted by asynchronous automata, viz. the class of finite prefix-closed trace languages. Therefore the complexity of the implementability problem for acyclic specifications is settled by the coNP-completeness result of Proposition 24.

As a remark, the above constructions cannot be used for the proof of Proposition 21 treating the case of *deterministic* specifications. \square

Proof of Proposition 26

We use a reduction from the emptiness problem for Turing machines:

Given an arbitrary Turing machine $M = (Q, \Gamma, \Gamma_0, \delta, q_0, B, F)$, we construct a context-free grammar G such that $L(G)$ is a trace language iff $L(M) = \emptyset$.

By definition, a *valid computation* of M is a string $\#w_1\#w_2^R\#w_3\#w_4^R\#\dots$ over the alphabet $Q \cup \Gamma \cup \{\#\}$ (with Q and Γ disjoint and $\#$ belonging to none of them) such that:

1. each w_i is an instantaneous description (ID) of M , that is, a string in $\Gamma^*Q\Gamma^*$ not ending with B (where B is the blank symbol),
2. w_1 is an initial ID, one of the form q_0x for $x \in \Gamma_0^*$,
3. w_n is a final ID, that is, one in $\Gamma^*F\Gamma^*$, and
4. $w_i \vdash_M w_{i+1}$ for $1 \leq i < n$ (w_i and w_{i+1} are consecutive IDs).

Let $\Sigma := Q \cup \Gamma \cup \{\#\}$. We choose a context-free grammar G over Σ able to compute exactly *all* the invalid computations of M . Such a grammar G exists according to the construction of [HU79, Lemma 8.7]. We have then that:

- if $L(M) = \emptyset$, then $L(G) = \Sigma^*$
- if $L(M) \neq \emptyset$, then $L(G) = \Sigma^* \setminus \{\text{the set of all valid computations of } M\}$.

The trick now is to choose a distribution over Σ such that $\#$ and q_0 are independent. We show that $L(M) = \emptyset$ iff $L(G)$ is a trace language. If $L(M) = \emptyset$, it is obvious that $L(G) = \Sigma^*$ is a trace language. If $L(M) \neq \emptyset$, then there is a valid computation of M , say w , which will not belong to $L(G)$. On one hand, by definition, w has the form $\#q_0w'$. On the other hand, $q_0\#w'$ is an invalid computation (any valid computation starts with $\#$) and therefore belongs to $L(G)$. So, we have that q_0 and $\#$ are independent and $q_0\#w' \in L(G)$, but $\#q_0w' \notin L(G)$, which means that $L(G)$ is not a trace language. \square

A.5 Details for Section 5

Definition 32. A (strong) *bisimulation* between a pair of transition systems $TS_1 = (Q_1, \Sigma, \rightarrow_1, I_1)$ and $TS_2 = (Q_2, \Sigma, \rightarrow_2, I_2)$ is a binary relation $\sim \subseteq Q_1 \times Q_2$ (for which we use the infix notation) such that:

- For each $q_1^{in} \in I_1$, there exists $q_2^{in} \in I_2$ such that $q_1^{in} \sim q_2^{in}$.
- For each $q_2^{in} \in I_2$, there exists $q_1^{in} \in I_1$ such that $q_1^{in} \sim q_2^{in}$.
- If $q_1 \sim q_2$ and $q_1 \xrightarrow{a}_1 q'_1$, there exists q'_2 such that $q_2 \xrightarrow{a}_2 q'_2$ and $q'_1 \sim q'_2$.
- If $q_1 \sim q_2$ and $q_2 \xrightarrow{a}_2 q'_2$, there exists q'_1 such that $q_1 \xrightarrow{a}_1 q'_1$ and $q'_1 \sim q'_2$.

Having defined the bisimulation, for a transition system TS one can define \sim_{TS} as the *largest* bisimulation between TS and itself. Constructing the largest bisimulation can be done in polynomial time. Since \sim_{TS} defines an equivalence relation on Q , we can construct (in the usual way) the quotient transition system TS/\sim_{TS} .

Synchronous Products of Transition Systems The synthesis problem modulo bisimulation is solved in [Muk02] for *deterministic* synchronous products by:

Theorem 33. [CMT99,Muk02] *Let $(\Sigma, Proc, \Delta)$ be a distribution and TS a transition system over Σ . Then, TS is bisimilar to a deterministic synchronous product of transition systems over Δ if and only if the bisimulation quotient TS/\sim_{TS} is deterministic and TS is language equivalent to a deterministic synchronous product over Δ .*

For a given transition system, checking the language equivalence with a *deterministic* synchronous product uses the same algorithm as for checking language equivalence with a synchronous product with only one initial state, i.e., the decision algorithm for Problem 16 (this follows from the observations that a deterministic synchronous product has only one initial state and that the local components $(TS_p)_{p \in Proc}$ can be determinized to build up a deterministic synchronous product).

Theorem 34. *The implementation problem for deterministic synchronous products modulo bisimulation is PSPACE-complete.*

Proof. The problem is in PSPACE: Checking the language equivalence of TS with a deterministic synchronous product is in PSPACE (the decision algorithm for Problem 16 is in PSPACE) and checking that TS/\sim_{TS} is deterministic takes polynomial time (constructing the largest bisimulation takes polynomial time).

The PSPACE-hardness proof is the similar to the proof of Proposition 21 observing that TS/\sim_{TS} is deterministic, whenever TS is deterministic. \square

Asynchronous Automata Given a distribution $(\Sigma, Proc, \Delta)$, we say a language $L \subseteq \Sigma^*$ is *forward-independence closed* iff $\forall w \in \Sigma^*, a, b \in \Sigma : wa, wb \in L \wedge a||b \Rightarrow wab \in L$. It is easy to see that the languages of *deterministic asynchronous automata* are forward-closed. Moreover, Zielonka’s construction [Zie87] can be slightly modified to obtain the following characterization:

Proposition 35. [Muk02, SEM03] *A language $L \subseteq \Sigma^*$ is accepted by a deterministic asynchronous automaton if and only if L is a prefix-closed regular forward-closed trace language.*¹⁰

The synthesis problem modulo bisimulation is solved in [Muk02] for *deterministic asynchronous automata* by:

Theorem 36. [Muk02] *Let $(\Sigma, Proc, \Delta)$ be a distribution and TS a transition system over Σ . Then, TS is bisimilar to a deterministic asynchronous automaton over Δ if and only if the bisimulation quotient TS/\sim_{TS} is deterministic and TS is language equivalent to a deterministic asynchronous automaton over Δ .*

Theorem 37. *The implementation problem for deterministic asynchronous automata modulo bisimulation can be decided in polynomial time.*

Proof. A polynomial algorithm to decide this problem works as follows:

Input: a distribution $(\Sigma, Proc, \Delta)$ and a transition system TS
Output: Is TS bisimilar to a deterministic asynchronous automaton?
<pre> Construct TS/\sim_{TS} if TS/\sim_{TS} is deterministic then if $L(TS/\sim_{TS})$ is a forward-closed trace language then output ‘yes’ else output ‘no’ else output ‘no’.</pre>

The algorithm is polynomial because the construction of TS/\sim_{TS} is polynomial, the first test is obviously polynomial, and the second test is polynomial for transition systems that are deterministic (which is the case for TS/\sim_{TS} , because of the if-nesting). The algorithm is correct according to Theorem 36, Proposition 35, and the language equality $L(TS/\sim_{TS}) = L(TS)$. \square

B Implementation

B.1 Code of the implementation described in Section 6

```

% Input:      a distribution (as a domain) and
%            a (possible nondeterministic) transition system TS
```

¹⁰This result together with Proposition 22 show that the nondeterministic asynchronous automata are strictly more expressive than their deterministic counterparts (as opposed to [Zie87] where they have same expressivity due to the flexibility of choosing a set of global accepting states).

```

% Question: is TS reachable, deadlock-free, and isomorphic
%           to an asynchronous automaton?
% Strategy: guess a set of equivalences satisfying AA1-AA2-AA3

%===specify the input as a database of facts
%...the translation of the distribution from Fig. 4
dom(a,1). dom(b,2).
%...the translation of the nondeterministic TS from Fig. 4
initialstate(1). initialstate(2).

```

B.2 Experimental results

Some preliminary experiments are presented in Table 9. We considered as benchmarks the parametrized specifications for the mutual exclusion problem given in [SEM03] and also for the dining philosophers problem¹¹. We present the times for running `smodels 2.27` on a Linux machine with a 2.4 GHz Intel processor and 2 GB of RAM. In case an execution did not terminate within 30 minutes, a ‘–’ is assigned in the table.

The first and second column of Table 9 give the instances of the problems considered together with the sizes of the *deterministic*¹² transition systems modeling them and the number of processes $|Proc|$ (shortly, $|P|$) of the distributions.

¹¹We considered only the safety requirement that no shared fork can be used simultaneously by the two philosophers that can have access to it.

¹²Despite our efforts to obtain nondeterministic specifications for the given problems (i.e., transition systems where nondeterministic choice really occurs), we ended up with deterministic transition systems (mainly due to complementation operations in the specifications).

Columns three and four show the times for solving Problem 28 by the heuristic of SYNASYNC that search for an ID and FD subautomaton, respectively a new SMOBELS-based logic implementation (using the idea of guessing the transitions of the subautomaton). For the instances of $\text{Mutex}(N)$, the heuristic of SYNASYNC performs better than the new one (the original transition systems already satisfies ID and FD and apparently this helps the heuristic). For $\text{Phil}(N)$ (where ID and FD does not hold initially), no solution for $N = 3, 4$ is found by SYNASYNC (fact denoted by ‘x’ in Table 9), because its current implementation employs a heuristic greedy algorithm which is *not a complete* method. The new implementation finds, in turn, solutions for $N = 3, 4$.

Columns five and six present the times for solving Problem 29 by two logic implementations in SMOBELS, based on Proposition 14 and Theorem 11, respectively. Since the specifications are *deterministic*, after we guess a subautomaton, we can implement either the (polynomial) characterization mentioned in Proposition 14 (see the details in [Mor99]) or the characterization of Theorem 11 (see the implementation given in the Appendix). As expected, due to the more difficult algorithms, we perform worse in the nondeterministic version. One optimization worth mentioning is that the logic program for the nondeterministic case has a tunable constant `max_local_state` which gives the maximum number of local states for each process (for Table 9, we used `max_local_state=3`). By tuning this constant, we can limit the logic program to look for synthesis solutions which are systems composed out of ‘small’ components.

To conclude, using a logic implementation we achieved the following:

- For SubautIDFD we have an implementation doing a complete search in the state space of solutions able to find solutions missed by the current implementation of the polynomial heuristic of SYNASYNC.
- For SubautAsync we are able to find solutions for $N = 3$. This is not impressive compared with SYNASYNC which for Mutex can go up to $N = 5$ (see [SEM03] for details). However, it beats the original construction of Zielonka which only works for $N = 2$ due to state space explosion. Moreover, the gain of this heuristic is that it makes a complete search in the state space of ‘small’ asynchronous automata whose global transition system is isomorphically embedded in the specification (so we are guaranteed solutions not exceeding the size of the specification).

The prototype implementations given in this work can be used as a starting point for more optimized synthesis procedures. Namely, the memory overheads involved in the implementation are (polynomial but still) very significant in larger instances. A special purpose synthesis procedure (i.e., a special purpose NP-solver) could potentially eliminate quite a lot of this memory overhead.

The benchmarks together with the above mentioned SMOBELS-based logic implementations can be found at:

<http://www.fmi.uni-stuttgart.de/szs/tools/synasync/smodels/>
